Selective Enumeration
A Formal Definition

Abstract

Selective enumeration is a method for reducing the number of cases required when performing a generate-and-test search to solve relational formulae. This paper gives a formal definition of selective enumeration and using that definition, proves soundness for each of the selective enumeration techniques developed.
Keywords

Relational calculus, exhaustive search, model checking, specification checking, constraint satisfaction.
1. Introduction

Sets, functions, and binary relations combine to provide a convenient, yet rigorous, framework for modeling software systems. Z [Spi92], probably the most widely used formal notation for describing software systems, is based entirely on these constructs. As sets, functions, and relations can all be described using relational formulae, I use the term *relational specification* to describe any specification built on these constructs.

Other software description notations also draw much of their expressive power from these constructs. Within the database community, the inter-relationships in a database schema are often specified using an entity-relationship diagram [Che76]. Given the name, it should not be surprising that entity-relationship diagrams can be clearly and succinctly described using relations.

More recently, UML [BJR97] has gathered great interest in the object community. Although UML combines several different notations to describe a single object design, many of these notations are built from sets, functions, and binary relations.

Despite the broad appeal of these constructs, little automated support is available for analyzing relational specifications. Theorem provers [ES94; SM96] can help, but they require enormous manual effort and provide little guidance to help repair faulty specifications. Model checkers [BC+92; CPS93] can analyze system specifications based on other formalisms, but no model checkers are available for relational specifications.

1.1 Generate-and-Test Searching

A method for solving relational formulae must lie at the core of any automated tool for analyzing relational specifications. The simplest approach is a generate-and-test search. A generate-and-test search generates every possible mapping of variables to values, called *assignments*, for a particular formula. The search then tests each generated assignment against that formula. The result of the search is a set of *satisfying assignments*, that is, assignments that give a true interpretation to the formula. A depth-first search can trivially generate a complete set of assignments, with each level of the search tree corresponding to a distinct variable in the formula.

Testing a single assignment against a formula is also straightforward, requiring only an implementation of the standard boolean, set and relational operations, making a generate-and-test search a simple solution.

However, using generate-and-test search as a solver presents two limitations. By its nature, a generate-and-test search will consider only some finite subset of the (generally infinite) possible assignment space. Although this limitation prevents a generate-and-test search from being a true verifier for infinite problems, it does not remove all practical applications. As I believe that many, if not most, errors in specifications can be demonstrated using only a small subset of the entire assignment space, a generate-and-test search can be the basis of a practical specification analysis tool.

The second limitation is the time required to generate and test all the assignments. This limitation has far more significant practical implications. Even with a simple specification (such as finder [JD95]) limited to only five underlying objects, the total number of assignments required to generate and test exceeds $10^{27}$.
Generating all $10^{27}$ assignments is clearly inconceivable, rendering naive exhaustive enumeration useless. Fortunately, the vast majority of these assignments are in some sense "duplicates" of other assignments. One assignment may be a permutation of another assignment. Or two assignments may share some common partial assignment, which itself determines the interpretation of the formula. Regardless of the nature of the duplication, generating only one assignment from each set of duplicate assignments is sufficient.

Selective enumeration is a generate-and-test search method that prevents the generation of most duplicates. By preventing the generation of these duplicates, selective enumeration is effective in solving many interesting relational formulae.

1.2 Alloc — An Example

This section introduces a very simple relational specification, which will be used to illustrate points throughout the remainder of this paper. This simple example describes a heap allocation system, such as malloc, in very general terms.

The specification is written in NP [JD96a], a relational specification language that is roughly a subset of Z. NP is limited to first-order objects, so, for example, there are no functions of functions. Figure 1 contains the NP specification for the heap allocation system.

The first line of the example introduces the two given types used in this specification, Addr and Value. A given type is a set of elements, with each element having no internal structure. Every element is contained in exactly one given type. All variables and expressions in NP are typed, indicating that they refer to one of three kinds of values. A variable or expression may refer to (1) an element of a given type, (2) a set of elements of a single given type, or (3) a relation that maps elements of a given type (the domain) to elements of a given type (the range). Relations can be restricted to functions, injections or bijections and they can be restricted to total or surjective relations.

When using NP, specifiers describe their system using a collections of schemas, which allow a simple structuring and composition of individual pieces of the specification, similar to the mechanism provided by Z. There are two independent characteristics that jointly classify schemas in NP. A schema is either a definition, which defines the system being specified, or a claim, which makes assertions about the system being specified. A schema, whether a definition or a claim, refers either to a single state or to a transition between two states. A transitional schema is called an operation and describes both a pre-state and a post-state. The specification given in Figure 1 contains examples of three of the four possible combinations of these characteristics, as explained in the following paragraphs.

All schemas have the same basic structure. The body of the schema comes after the name of the schema and is enclosed in square brackets ([ ]). The body is separated into two sections by a single vertical bar (|). The first section defines the variables used in the schema, whereas the second section gives a collection of relational formulae that must all be satisfied in any system described by this specification.

In the example given in Figure 1, Heap is a definitional schema that describes the basic structure of a heap. Heap introduces two variables, usage and used. The variable usage denotes a function mapping addresses (elements of Addr) to their values (elements of Value). The other variable, used, denotes a set that contains all of the addresses currently in use. Heap also defines
Figure 1: A trivial NP specification describing a heap allocation system. Addr and Value are the given types. Heap describes the basic structure being manipulated, Alloc describes an allocation operation, and uniqueAddrAlloc is a claim about the specification.

A single formula that describes a relationship that must hold in all valid heaps: the set of addresses in use is exactly the set of addresses currently mapped, that is, the domain of the function $usage$. 

Alloc is an operation that describes the change in a heap when a new piece of memory is allocated. As Alloc refers to Heap in its declaration section, Alloc inherits all of the variables defined by Heap. Within Alloc, the pre-state is referenced using the simple variable names, whereas the post-state is referenced using primed variables, such as $usage'$. Operations are indicated by the presence of a (possibly empty) parameter list. The parameter list for Alloc defines a single parameter, $addr$, which is the newly allocated address.

There are two formulas within Alloc. The first ($used <: usage' = usage$) guarantees that the allocation does not change any existing mappings. The second formula ($used'' = used U addr$)
indicates that the newly allocated address is now considered to be in use (in addition to any addresses already in use).

The third schema, uniqueAddrAlloc, is a claim that asserts that the newly allocated address is not in use prior to the allocation.

1.3 Reducing the Search to Validate uniqueAddrAlloc

A common analysis of NP specifications is to attempt to validate claims such as uniqueAddrAlloc. A claim is valid if there are no assignments that satisfy the negation of the claim. Nitpick [JD96b], the tool that I have implemented to analyze relational specifications, validates claims (within user specified finite bounds) using selective enumeration to solve the negation of the claim. The satisfying assignments for the negation of the claim are counterexamples of the claim itself.

Selective enumeration recognizes and exploits two basic kinds of duplications: partial assignment duplicates and permutation duplicates. Two assignments are partial assignment duplicates if they share a common mapping of values for a subset of the variables (called a partial assignment) and that partial assignment itself determines the value of the formula.

The simplest way of exploiting partial assignment duplicates is by exploiting derived variables [JD95]. In many specifications, the values of some variables are defined constructively, that is, their value is constrained to be equal to a function of the values of the other variables. Variables with a constructive definition are called derived variables. Given the bindings for the other variables, the search can directly construct the value of a derived variable, rather than generating many possible values and testing each one. For example, the formula used = dom usage appears in the schema Heap. Therefore, the value of used must be exactly the domain of the value of usage in any counterexample to uniqueAddrAlloc. Assuming that usage is bound prior to used being generated, the value of used can be directly computed.

As is obvious from this example, selective enumeration requires the imposition of a variable ordering. Although any ordering is legal for selective enumeration, some orderings yield a much greater reduction in the number of assignments generated than indicated by other orderings.\(^\text{2}\)

Because of the constraint a not in used, the value of a must be an element of the value of used for any counterexample to uniqueAddrAlloc. Although this constraint does not limit the possible values of a to a single value, the constraint can be used to limit the values actually generated during the search. Bounded generation uses constraints from the formula to limit the values generated. Assuming that used is bound before the value of a is generated, bounded generation will generate each element in the set that is the value of used, instead of each value in the given type Addr.

A second opportunity for bounded generation exists in uniqueAddrAlloc. The first formula in Alloc, used <: usage' = usage, must be true in any counterexample to uniqueAddrAlloc. To

\begin{footnotesize}
1. The <: operator is the domain restriction operator. The result of this expression is a relation that includes all of the pairs in the relation given as the second argument whose first element is contained in the set given as the first argument. For the formal definition of this and other operators, refer to Definition 16 on page 14.
2. The mechanism for choosing an ordering is beyond the scope of this paper. Nitpick uses a heuristic to choose the ordering, as computing an optimal ordering is factorial in the number of variables.
\end{footnotesize}
simplify the implementation, bounded generation does not directly take advantage of this constraint; instead, this constraint implies a weaker constraint, $usage <= usage'$. Bounded generation uses this weaker constraint to limit both the domain and range of any value generated for $usage$ to be subsets of the domain and range of the value of $usage'$.

Derived variable analysis and bounded generation cannot fully exploit all formulae within a specification. If these formulae do not depend on all the variables, they still present an opportunity for reducing the assignments to be generated. Short circuiting [DJ96] does not reduce the number of values generated for any variables involved in the formula, as would bounded generation. Instead, short circuiting prevents generation of values for any subsequent variables when the partial assignment cannot satisfy the formula.

An example of short circuiting can be found for the constraint on $usage$ and $usage'$ that initiated the second bounded generation example. Although bounded generation will guarantee that $dom usage <= dom usage'$ and $ran usage <= ran usage'$, this constraint does not guarantee that $usage <= usage'$. Once $usage$ and $usage'$ have both been generated, short circuiting evaluates the constraint $usage <= usage'$ for the resulting partial assignment. Short circuiting will terminate the current path of the search for any partial assignments not satisfying the constraint. Similarly, once $usage$, $usage'$, and $used$ have been generated, short circuiting will check the full constraint,

$used <= usage' = usage$. By utilizing all three techniques, selective enumeration can eliminate all partial assignment duplicates available with the selected ordering.

The second form of duplication is called permutation duplication. Because each element in a given type is unstructured, exchanging a pair of elements throughout an assignment does not change the interpretation of the formula for that assignment. Isomorph elimination [JJD96;JJD98] prevents the generation of most\(^3\) values that are permutations of other values already generated.

As an example of isomorph elimination, consider the values generated for $usage'$. If Addr and Value are limited to three elements apiece, it is necessary to generate 64 ($\#domain^{\#range+1}$) values for the partial function $usage'$ without isomorph elimination. With isomorph elimination, on the other hand, only the following seven values need be generated:

\[
\begin{align*}
usage' &= \emptyset \\
usage' &= \{ (a_0, v_0) \} \\
usage' &= \{ (a_0, v_0), (a_1, v_1) \} \\
usage' &= \{ (a_0, v_0), (a_1, v_0) \} \\
usage' &= \{ (a_0, v_0), (a_1, v_1), (a_2, v_2) \} \\
usage' &= \{ (a_0, v_0), (a_1, v_0), (a_2, v_1) \} \\
usage' &= \{ (a_0, v_0), (a_1, v_0), (a_2, v_0) \}
\end{align*}
\]

The result of this reduced search is illustrated in Figure 2 and Figure 3. Figure 2 demonstrates the search until the first counterexample is found. When the number of elements in Addr and Value are limited to three apiece, derived variables and bounded generation reduce the search to find the first counterexample from 13,851 assignments to just 3. Figure 3 expands the tree for one more value of $usage'$, exhibiting the further advantages of short circuiting and isomorph elimination.

---

3. The current implementation of isomorph elimination does not consider all possible permutations. In particular, only products of selected single permutations are considered.
Figure 2: The search tree for finding a counterexample to the claim uniqueAddrAlloc. The variables \texttt{used}' and \texttt{used} are derived; their values can be directly computed from the earlier assignments. Bounded generation limits the domain and range of the values generated for \texttt{usage} to a subset of the domain and range used in \texttt{usage}'. Similarly, bounded generation limits the values considered for \texttt{a} to the elements in the value of \texttt{used}. The first two paths down the search tree result in \texttt{used} being empty, leaving no possible values for \texttt{a}. The first counterexample discovered is shown in a heavier box.
1.4 Related Work

The model-generation community [Zha96; ZZ95; Sla94] has addressed a problem that is similar to the relational formula satisfaction problem addressed by selective enumeration. A model-generation tool searches for a satisfying assignment, or model, for a formula. The logic supported by the model-generation tools varies from the logic supported by NP. Variables are allowed to be arbitrary arity functions in most of these tools, whereas NP directly supports only unary functions. (Arbitrary arity functions can be expressed in NP through careful encoding, but the resultant formula is hard to understand and selective enumeration is particularly inefficient at analyzing such formulae.) NP, on the other hand, adds support for transitive closure, which is difficult or impossible to express generally in the model-generation languages. There is also a difference in apparent goals: selective enumeration is best suited for solving formulae with several variables using a relatively small scope, whereas the model generators appear targeted towards formulae with few variables (frequently one) using a larger scope.

Despite these differences, some of the model generators use an approach similar to the one used in selective enumeration. Zhang [Zha96], in particular, used a similar set of reduction techniques in FALCON. FALCON includes a simpler form of isomorph elimination, a direct equivalent to derived-variable construction and a backtracking feature that is similar to short circuiting. Slaney [Sla94] also uses a backtracking approach in Finder; he achieves reductions similar to those gained with bounded generation by separating the enumeration of functions into separate boolean variables, each representing a single maplet.

Jipsen's approach [Jip92] finds a Boolean algebra with operators (BAO) that satisfies a set of first-order equations. His approach does not require finite bounds, and thus can be used as a true verifier. As the relational calculus can be embedded in BAO, this approach will also solve relational formulae. However, there are a number of difficulties with Jipsen's work. His approach has never been proved complete — it may never terminate for an unsatisfiable system of equations. As transitive closure is not supported within BAO, most of our specifications could not be expressed in full generality. No experimental results are provided, so it is not possible to compare his approach to selective enumeration, even for the finite domain.

The most general related problem is the well known boolean-satisfiability problem. Although the problem itself is NP-complete, researchers have taken two major approaches to achieve an effective solution in realistic time for many formulae. One approach, found in [SLM92] among others, provides an unsound solver, which may fail to return a solution even if one exists. In the other widespread approach, a structure or algorithm provides significantly reduced exponential growth for common formulae, although the worst-case performance may lag even the most naive approach. Binary decision diagrams (or BDDs) [Bry92] are a popular structure that provides this generally reduced exponential growth.

There is a straightforward translation from relational formulae to boolean formulae, so any of the boolean satisfiability approaches can be applied to solve any relational formulae. This conversion loses much of the higher level semantics of the relational formulae. Selective enumeration uses these semantics to produce its reductions. As given in [DJJ96], translating a relational formula into the corresponding boolean one and solving the boolean formula using BDDs required approximately the same time as solving the relational formula directly using selective enumeration. The introduction of bounded generation and an improved isomorph-elimination technique has moved the balance significantly towards selective enumeration. Although it is possible that further effort on the BDD version could similarly reduce the time required, I believe that the additional semantics available in the relational formula will give an advantage to selective enumeration.

Solving a relational formula could be structured as a constraint satisfaction problem. Traditional
constraint satisfaction approaches [Kum92; Mac92], used to solve problems such as shape recognition [Wal75] or job shop scheduling [SF91], support only a much more limited constraint language. Finite constraint satisfaction, the area most similar to selective enumeration, allows only a restricted subset of Horn clauses to express the constraints. For most of the existing constraint satisfaction algorithms, all constraints must be binary (involve no more than two variables). Constraint satisfaction algorithms also typically require a complete enumeration of possible values for each variable, which can be prohibitively expensive for the relation-typed variables commonly found in NP specifications.

There are significant similarities between the approaches taken in constraint satisfaction and the approach taken in selective enumeration. Backtracking in constraint satisfaction is a direct equivalent of short circuiting in selective enumeration, requiring the same care in selecting a variable ordering. The standard constraint propagation algorithms, including arc consistency and k-consistency, are strongly reminiscent of bounded generation. They are limited, however, to the weaker constraint language.
2. Basic Definitions

This section develops the basic terminology for defining selective enumeration precisely. In the following sections, I use this terminology to define each technique that implements selective enumeration. I also prove the soundness of each of these techniques.

This section begins by defining the basic concepts underlying any generate-and-test search. From these, I develop precise definitions of the generators and duplications that are the essence of selective enumeration. A formal definition of soundness follows naturally from these definitions.

2.1 Values and Variables

The search chooses values constructed from the finite universe \( \mathcal{U} \) of atomic elements. Each element within \( \mathcal{U} \) is itself unstructured. In this initial analysis, I ignore the type distinctions between elements. Therefore, for the simple alloc example described in the prior section, \( \mathcal{U} \) is the union of the \( \text{Addr} \) and \( \text{Value} \) sets. In Section 6, I will re-introduce given types to differentiate the elements of \( \mathcal{U} \).

There are three kinds of values: (1) atomic elements of \( \mathcal{U} \), (2) sets of atomic elements, or (3) binary relations on the atomic elements.

**Definition 1:**

\[
\begin{align*}
\text{Value}_{\text{scalar}} &= \mathcal{U} \\
\text{Value}_{\text{set}} &= \mathcal{P}(\mathcal{U}) \\
\text{Value}_{\text{rel}} &= \mathcal{P}(\mathcal{U} \times \mathcal{U}) \\
\text{Value} &= \text{Value}_{\text{scalar}} \cup \text{Value}_{\text{set}} \cup \text{Value}_{\text{rel}}
\end{align*}
\]

Each claim or schema in a specification defines a set of variables. I divide the complete collection of variables into three sets based on the kind of value they denote: \( \text{Var}_{\text{scalar}} \), \( \text{Var}_{\text{set}} \), and \( \text{Var}_{\text{rel}} \).

The intuitive relationship between these variables and the corresponding values will be maintained; a variable in \( \text{Var}_{\text{scalar}} \) will only be bound to an atomic element whereas a variable in \( \text{Var}_{\text{set}} \) will only be bound to a set of atomic elements.

**Definition 2:**

\[ \text{Variable} = \text{Var}_{\text{scalar}} \cup \text{Var}_{\text{set}} \cup \text{Var}_{\text{rel}} \]

**Definition 3:**

\[ N = |\text{Variable}| \]

For the claim uniqueAddrAlloc from Figure 1, \( N \) is 5 and the variables are

\[
\begin{align*}
\text{Var}_{\text{scalar}} &= \{ a \} \\
\text{Var}_{\text{set}} &= \{ \text{used, used}' \} \\
\text{Var}_{\text{rel}} &= \{ \text{usage, usage}' \}
\end{align*}
\]

To perform the search, the variables need to be ordered. This order corresponds to the ordering used in the search tree.

**Definition 4:**

\[ \text{Ord}: \text{Variable} \rightarrow 1 \ldots N \]

For the uniqueAddrAlloc example, I will use the ordering from the search illustrated in Figure 2 and Figure 3:
Ord = { usage'→1, used'→2, usage→3, used→4, a→5 }

A useful construct is the ordering-based subsets of variables.

**Definition 5:** \( \text{Var}_1 = \{ v \mid 1 < \text{Ord}(v) < i \} \)

By convention, \( \text{Var}_2 \) is the empty set of variables. Using the \( \text{Ord} \) for uniqueAddrAlloc from the prior paragraph, the value for \( \text{Var}_3 \) is

\( \text{Var}_3 = \{ \text{usage}', \text{used}', \text{usage} \} \)

### 2.2 Language

The next basic element is the language used to express the formula itself. The NP language is intended for human consumption; structures such as schemas offer no additional expressive power. Nitpick translates each specification from the NP language into a simpler formula language. To further simplify this analysis, I define only a subset of the formula language here. Extending this analysis to include the entire formula language is a straightforward exercise.

The alphabet of the simplified formula language includes the variables and the operators.

\( \mathcal{A} = \text{Variable} \cup \{ \{ \}, \text{dom}, \text{ran}, \text{func}, \text{U}, \&, , <, =, =\!, \text{Un}, (, ), \text{and}, \text{or}, \text{not} \} \)

The foundation of the language is the terms. Terms describe all of the values that can be constructed using this language. As with other items, terms are divided into three categories: \( \text{Term}_{\text{scalar}}, \text{Term}_{\text{set}}, \) and \( \text{Term}_{\text{rel}}. \)

**Definition 6:** \( \text{Term} = \text{Term}_{\text{scalar}} \cup \text{Term}_{\text{set}} \cup \text{Term}_{\text{rel}}, \) where

\( \text{Term}_{\text{scalar}}, \text{Term}_{\text{set}}, \) and \( \text{Term}_{\text{rel}} \) are defined by the BNF grammars

\[
\begin{align*}
\text{Term}_{\text{scalar}} & ::= \text{Var}_{\text{scalar}} \\
\text{Term}_{\text{set}} & ::= \text{Var}_{\text{set}} | \{ \text{Term}_{\text{scalar}} \} | \{ \} | \text{Un} | (\text{Term}_{\text{set}} \cup \text{Term}_{\text{set}}) | (\text{Term}_{\text{set}} \& \text{Term}_{\text{set}}) | (\text{Term}_{\text{set}} \setminus \text{Term}_{\text{set}}) | \text{Term}_{\text{rel}} (\text{Term}_{\text{scalar}}) | \text{dom} \text{Term}_{\text{rel}} | \text{ran} \text{Term}_{\text{rel}} \\
\text{Term}_{\text{rel}} & ::= \text{Var}_{\text{rel}} | (\text{Term}_{\text{set}} <: \text{Term}_{\text{rel}})
\end{align*}
\]

As an overview, \( \text{Un} \) is the universe of possible values of the appropriate type, \( \& \) is the intersection operator, and \( \text{Term}_{\text{rel}} (\text{Term}_{\text{scalar}}) \) gives the relational image. The complete, formal definitions of the operators are given in the definitions starting on page 13.

Atomic formulae are constructed from terms.

**Definition 7:** AtomicFormula, the set of atomic formulae, is defined by the BNF grammar

\[
\begin{align*}
\text{AtomicFormula} & ::= \text{Term}_{\text{scalar}} \text{ in } \text{Term}_{\text{set}} | \text{Term}_{\text{scalar}} = \text{Term}_{\text{scalar}} | \\
& | \text{Term}_{\text{set}} = \text{Term}_{\text{set}} | \text{Term}_{\text{set}} \subseteq \text{Term}_{\text{set}} | \\
& | \text{Term}_{\text{rel}} = \text{Term}_{\text{rel}} | \text{func} \text{Term}_{\text{rel}}
\end{align*}
\]

Finally, Wffs in the formula language are built from atomic formulae.
**Definition 8:** Wff, the set of well-formed formulae, is defined by the BNF grammar

\[
\text{Wff} := \text{AtomicFormula} \mid \text{not Wff} \rightarrow \text{Wff} \mid ( \text{Wff and Wff} ) \mid ( \text{Wff or Wff} )
\]

For any formula in the language, there is a unique derivation for that formula given by this grammar. The claim \text{uniqueAddrAlloc} from Figure 1, which is written in NP, is translated into the formula language as

**Formula 1:** ( not ( ( \text{dom usage} = \text{used} and \text{dom usage} = \text{used}') 
and ( \text{func usage} and \text{func usage} = \text{used}') ) or 
(not ( ( \text{dom usage} = \text{used} and \text{dom usage} = \text{used}') and 
( \text{used} <= \text{usage}' ) = \text{usage} and \text{used}' = (\text{used} U \{a\}) ) 
or a \in \text{used} ) )

For the formula language, the set of free variables for a formula is exactly the set of variables used in the formula.

**Definition 9:** The free variables of a term, \( FV(\tau) : \text{Term} \rightarrow \mathbb{P}\text{Variable} \), is defined as

- if \( \tau \) is \( v \) where \( v \in \text{Variable} \)
  \[
  \{ v \}
  \]
- if \( \tau \) is \( \{ \tau_1 \} \) where \( \tau_1 \in \text{Term}_{\text{scalar}} \)
  \( FV(\tau_1) \)
- if \( \tau \) is \( \{ \} \)
  \( \emptyset \)
- if \( \tau \) is \( \text{Un} \)
  \( \emptyset \)
- if \( \tau \) is \( ( \tau_1 \ \text{op} \ \tau_2 ) \) where \( \tau_1, \tau_2 \in \text{Term} \) and \( \text{op} \) is one of \( \cup, \& \), \( <= \), or \( \setminus \)
  \( FV(\tau_1) \cup FV(\tau_2) \)
- if \( \tau \) is \( \text{op} \ \tau_1 \) where \( \tau_1 \in \text{Term}_{\text{rel}} \) and \( \text{op} \) is either \( \text{dom} \) or \( \text{ran} \)
  \( FV(\tau_1) \)
- if \( \tau \) is \( \tau_1 (\tau_2) \) where \( \tau_1 \in \text{Term}_{\text{rel}}, \tau_2 \in \text{Term}_{\text{scalar}} \)
  \( FV(\tau_1) \cup FV(\tau_2) \)

**Definition 10:** The free variables of a formula, \( FV(\phi) : \text{Wff} \rightarrow \mathbb{P}\text{Variable} \), is defined as

- if \( \phi \) is \( \tau_1 \ \text{op} \ \tau_2 \) where \( \tau_1, \tau_2 \in \text{Term} \) and \( \text{op} \) is either \( =, \text{in}, \text{or} \leq \)
  \( FV(\tau_1) \cup FV(\tau_2) \)
- if \( \phi \) is \( \text{func} \ \tau_1 \) where \( \tau_1 \in \text{Term}_{\text{rel}} \)
  \( FV(\tau_1) \)
- if \( \phi \) is \( ( \phi_1 \ \text{op} \ \phi_2 ) \) where \( \phi_1, \phi_2 \in \text{Wff} \) and \( \text{op} \) is either and or or
  \( FV(\phi_1) \cup FV(\phi_2) \)
- if \( \phi \) is \( \text{not} \ \phi_1 \) where \( \phi_1 \in \text{Wff} \)
  \( FV(\phi_1) \)
2.3 Assignments

A generate-and-test search solves a formula by generating assignments, then interpreting the formula for each assignment generated. An assignment is a mapping from variables to appropriate values. An assignment can be a full assignment, mapping all variables to appropriate values, or it can be a partial assignment, mapping only a subset of the variables to values.

**Definition 11**: \( S : \text{Variable} \rightarrow \text{Value} = \{ v \mapsto x \mid v \in \text{Var}_{\text{scalar}} \Rightarrow x \in \text{Value}_{\text{scalar}} \land v \in \text{Var}_{\text{set}} \Rightarrow x \in \text{Value}_{\text{set}} \land v \in \text{Var}_{\text{rel}} \Rightarrow x \in \text{Value}_{\text{rel}} \} \)

\( S \), therefore, is the set of all well-typed assignments. A useful decomposition of \( S \) is based on what variables are actually mapped.

**Definition 12**: \( S_i = \{ s \in S \mid \text{dom } s = \text{Var}_i \} \)

\( S_i \) is the set of all assignments that map exactly the first \( i \) variables, as defined by \( \text{Ord} \). The assignments on the \( i^{\text{th}} \) level of the search tree are drawn from \( S_i \). Two such sets are of particular interest: \( S_0 \) contains only the empty assignment and \( S_N \) contains all full assignments.

2.4 Interpretation

A precise semantics of the formula language is needed to analyze the assignments. A formula is interpreted as true, false or unknown for any given assignment. Intuitively, the interpretation of a formula may be unknown if any of the free variables of the formula are not mapped by the assignment. Otherwise, each variable in the formula is replaced by the corresponding value from the assignment and the formula is evaluated using the usual semantics for relational formulae.

The interpretation of a formula is dependent on the interpretation of each term. The interpretation of a term in the formula language is given as \( \overline{s} (\tau) \). \( \overline{s} \) is the union of three functions: \( \overline{s}_{\text{scalar}}, \overline{s}_{\text{set}}, \) and \( \overline{s}_{\text{rel}} \).

**Definition 13**: \( \overline{s} = \overline{s}_{\text{scalar}} \cup \overline{s}_{\text{set}} \cup \overline{s}_{\text{rel}} \)

**Definition 14**: \( \overline{s}_{\text{scalar}} (\tau) : \text{Term}_{\text{scalar}} \rightarrow \text{Value}_{\text{scalar}} \cup \{ \text{unknown} \} = \)

\[
\begin{align*}
\text{if } \tau & \in \text{Var}_{\text{scalar}} \\
\overline{s}(\tau) & \quad \text{if } \tau \in \text{dom } s \\
\text{unknown} & \quad \text{otherwise}
\end{align*}
\]

**Definition 15**: \( \overline{s}_{\text{set}} (\tau) : \text{Term}_{\text{set}} \rightarrow \text{Value}_{\text{set}} \cup \{ \text{unknown} \} = \)

\[
\begin{align*}
\text{if } \tau & \text{ is } v \text{ where } v \in \text{Var}_{\text{set}} \\
\overline{s}(v) & \quad \text{if } v \in \text{dom } s \\
\text{unknown} & \quad \text{otherwise}
\end{align*}
\]

\[
\begin{align*}
\text{if } \tau & \in \{ \tau_1 \} \text{ where } \tau_1 \in \text{Term}_{\text{scalar}} \\
\{ x \mid x = \overline{s}_{\text{scalar}} (\tau_1) \} & \quad \text{if } \overline{s}_{\text{scalar}} (\tau_1) \neq \text{unknown} \\
\text{unknown} & \quad \text{otherwise}
\end{align*}
\]
if \( \tau \) is \( \emptyset \)
\[ \emptyset \]

if \( \tau \) is \( \text{Un} \)
\[ \mathcal{U} \]

if \( \tau \) is \( \tau_1 \cup \tau_2 \) where \( \tau_1, \tau_2 \in \text{Term}_{\text{set}} \)
\[ \{ x \mid x \in \overline{S}_{\text{set}}(\tau_1) \lor x \in \overline{S}_{\text{set}}(\tau_2) \} \]
if \( \overline{S}_{\text{set}}(\tau_1) \neq \text{unknown} \land \overline{S}_{\text{set}}(\tau_2) \neq \text{unknown} \)
unknown otherwise

if \( \tau \) is \( \tau_1 \wedge \tau_2 \) where \( \tau_1, \tau_2 \in \text{Term}_{\text{set}} \)
\[ \{ x \mid x \in \overline{S}_{\text{set}}(\tau_1) \land x \in \overline{S}_{\text{set}}(\tau_2) \} \]
if \( \overline{S}_{\text{set}}(\tau_1) \neq \text{unknown} \land \overline{S}_{\text{set}}(\tau_2) \neq \text{unknown} \)
unknown otherwise

if \( \tau \) is \( \tau_1 \setminus \tau_2 \) where \( \tau_1, \tau_2 \in \text{Term}_{\text{set}} \)
\[ \{ x \mid x \in \overline{S}_{\text{set}}(\tau_1) \land x \notin \overline{S}_{\text{set}}(\tau_2) \} \]
if \( \overline{S}_{\text{set}}(\tau_1) \neq \text{unknown} \land \overline{S}_{\text{set}}(\tau_2) \neq \text{unknown} \)
unknown otherwise

if \( \tau \) is \( \text{dom} \tau_1 \) where \( \tau_1 \in \text{Term}_{\text{rel}} \)
\[ \{ x \mid \exists y. (x, y) \in \overline{S}_{\text{rel}}(\tau_1) \} \]
if \( \overline{S}_{\text{rel}}(\tau_1) \neq \text{unknown} \)
unknown otherwise

if \( \tau \) is \( \text{ran} \tau_1 \) where \( \tau_1 \in \text{Term}_{\text{rel}} \)
\[ \{ y \mid \exists x. (x, y) \in \overline{S}_{\text{rel}}(\tau_1) \} \]
if \( \overline{S}_{\text{rel}}(\tau_1) \neq \text{unknown} \)
unknown otherwise

if \( \tau \) is \( \tau_1 (\tau_2) \) where \( \tau_1, \tau_2 \in \text{Term}_{\text{rel}} \land \tau_2 \in \text{Term}_{\text{scalar}} \)
\[ \{ y \mid (\overline{S}_{\text{scalar}}(\tau_2), y) \in \overline{S}_{\text{rel}}(\tau_1) \} \]
if \( \overline{S}_{\text{rel}}(\tau_1) \neq \text{unknown} \land \overline{S}_{\text{scalar}}(\tau_2) \neq \text{unknown} \)
unknown otherwise

**Definition 16:** \( \overline{S}_{\text{rel}}(\tau) : \text{Term}_{\text{rel}} \rightarrow \text{Value}_{\text{rel}} \cup \{ \text{unknown} \} = \)

if \( \tau \in \text{Var}_{\text{rel}} \)
\[ \overline{s}(\tau) \]
if \( \tau \in \text{dom} s \)
unknown otherwise

if \( \tau \) is \( \tau_1 <: \tau_2 \) where \( \tau_1, \tau_2 \in \text{Term}_{\text{set}} \land \tau_2 \in \text{Term}_{\text{rel}} \)
\[ \{ (x, y) \mid x \in \overline{S}_{\text{set}}(\tau_1) \land (x, y) \in \overline{S}_{\text{rel}}(\tau_2) \} \]
if \( \overline{S}_{\text{set}}(\tau_1) \neq \text{unknown} \land \overline{S}_{\text{rel}}(\tau_2) \neq \text{unknown} \)
unknown otherwise

The three \( \overline{S} \) functions derive from directly \( S \). Therefore, each assignment \( S \) induces a corresponding \( \overline{S} \) function.

The interpretation of a formula for an assignment is given using \( \overline{\phi}[S] \), where \( S \in S \) and \( \phi \in \text{Wff} \). It follows from the \( S \) functions.

**Definition 17:** \( \overline{\phi}[S] : S \times \text{Wff} \rightarrow \{ \text{true}, \text{false}, \text{unknown} \} = \)
if $\phi$ is $\tau_1 = \tau_2$ where $\tau_1, \tau_2 \in \text{Term}_{\text{scalar}}$
true  
if $s_{\text{scalar}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{scalar}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{scalar}}(\tau_1) = s_{\text{scalar}}(\tau_2)$
false  
if $\overline{s}_{\text{scalar}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{scalar}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{scalar}}(\tau_1) \neq \overline{s}_{\text{scalar}}(\tau_2)$
unknown  
otherwise

if $\phi$ is $\tau_1 \in \tau_2$ where $\tau_1 \in \text{Term}_{\text{scalar}}$ and $\tau_2 \in \text{Term}_{\text{set}}$
true  
if $s_{\text{scalar}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{scalar}}(\tau_1) \in s_{\text{set}}(\tau_2)$
false  
if $\overline{s}_{\text{scalar}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{scalar}}(\tau_1) \notin s_{\text{set}}(\tau_2)$
unknown  
otherwise

if $\phi$ is $\tau_1 = \tau_2$ where $\tau_1, \tau_2 \in \text{Term}_{\text{set}}$
true  
if $s_{\text{set}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_1) = s_{\text{set}}(\tau_2)$
false  
if $\overline{s}_{\text{set}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_1) \neq \overline{s}_{\text{set}}(\tau_2)$
unknown  
otherwise

if $\phi$ is $\tau_1 \subseteq \tau_2$ where $\tau_1, \tau_2 \in \text{Term}_{\text{set}}$
true  
if $s_{\text{set}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_1) \subseteq s_{\text{set}}(\tau_2)$
false  
if $\overline{s}_{\text{set}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{set}}(\tau_1) \nsubseteq s_{\text{set}}(\tau_2)$ ∧  
$s_{\text{set}}(\tau_1) \neq \overline{s}_{\text{set}}(\tau_2)$
unknown  
otherwise

if $\phi$ is $\tau_1 = \tau_2$ where $\tau_1, \tau_2 \in \text{Term}_{\text{rel}}$
true  
if $s_{\text{rel}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{rel}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{rel}}(\tau_1) = s_{\text{rel}}(\tau_2)$
false  
if $\overline{s}_{\text{rel}}(\tau_1) \neq \text{unknown}$ ∧  
$s_{\text{rel}}(\tau_2) \neq \text{unknown}$ ∧  
$s_{\text{rel}}(\tau_1) \neq \overline{s}_{\text{rel}}(\tau_2)$
unknown  
otherwise
if $\phi$ is func $\tau_1$ where $\tau_1 \in \text{Term}_{\text{rel}}$
  true
  if $\overline{S}_{\text{rel}}(\tau_1) \neq \text{unknown} \land$
  $\forall x,y,z \in U$,
  $((x,y) \in S_{\text{rel}}(\tau_1) \land$
  $(x,z) \in \overline{S}_{\text{rel}}(\tau_1))$
  $\Rightarrow y = z$
  false
  if $\overline{S}_{\text{rel}}(\tau_1) \neq \text{unknown} \land$
  $\forall x,y \in U, \exists z \in U, y \neq z \land$
  $((x,y) \in \overline{S}_{\text{rel}}(\tau_1) \land$
  $(x,z) \in S_{\text{rel}}(\tau_1))$

unknown

otherwise

if $\phi$ is ( $\phi_1$ and $\phi_2$ ) where $\phi_1, \phi_2 \in \text{Wff}$
  true
  if $\models \phi_1[s] = \text{true} \land \models \phi_2[s] = \text{true}$
  false
  if $\models \phi_1[s] = \text{false} \lor \models \phi_2[s] = \text{false}$
  unknown
  otherwise

if $\phi$ is ( $\phi_1$ or $\phi_2$ ) where $\phi_1, \phi_2 \in \text{Wff}$
  true
  if $\models \phi_1[s] = \text{true} \lor \models \phi_2[s] = \text{true}$
  false
  if $\models \phi_1[s] = \text{false} \land \models \phi_2[s] = \text{false}$
  unknown
  otherwise

if $\phi$ is not $\phi_1$ where $\phi_1 \in \text{Wff}$
  true
  if $\models \phi_1[s] = \text{true}$
  false
  if $\models \phi_1[s] = \text{false}$
  unknown
  otherwise

As an example, consider the negation of Formula 1 (derived from uniqueAddrAlloc) given by Formula 2:

**Formula 2**: $\phi = ( (\text{dom usage} = \text{used and dom usage'} = \text{used'}) \land$
  (func usage and func usage') and
  ( ( used $\Leftarrow$ usage') = usage and used' = (used U \{a\})
  and a in used ))

This formula can be interpreted using any valid assignment. Assuming $a_0$ and $v_0$ are elements of $U$, three possible interpretations are

$\models \phi[\{\} ] = \text{unknown}$

$\models \phi[\{\text{usage'})\mapsto\{(a_0, v_0)\}, \text{used')\mapsto\{\}\} ] = \text{false}$

$\models \phi[\{\text{usage'})\mapsto\{(a_0, v_0)\}, \text{used')\mapsto\{(a_0\},$

usage$\mapsto\{(a_0, v_0)\}, \text{used}\mapsto\{(a_0\}, a\mapsto a_0 \} ] = \text{true}$

If the assignment maps all of the free variables in the formula, the interpretation will be either true or false, but not unknown.

**Theorem 1**: $\forall s \in S, \tau \in \text{Term.FV}(\tau) \subseteq \text{dom s} \Rightarrow S(\tau) \neq \text{unknown}$

**Proof**: By structural induction.
If τ is v where v ∈ Variable
  By definition, FV(τ) = \{ v \}
  As FV(τ) ⊆ dom s, v ∈ dom s
  By definition of \( \overline{s} \), v ∈ dom s ⇒ \( \overline{s}(\tau) \neq \text{unknown} \).

if τ is \( \tau_1 \cup \tau_2 \) where \( \tau_1, \tau_2 \in \text{Term}_s \)
  By definition of FV, FV(\( \tau_1 \)) ⊆ FV(τ) and FV(\( \tau_2 \)) ⊆ FV(τ)
  Therefore, FV(\( \tau_1 \)) ⊆ dom s and FV(\( \tau_2 \)) ⊆ dom s
  Therefore, by induction, \( \overline{s}(\tau_1) \neq \text{unknown} \) and \( \overline{s}(\tau_2) \neq \text{unknown} \)
  By definition of \( \overline{s} \), \( \overline{s}(\tau) \neq \text{unknown} \)

Other productions follow similarly

**Theorem 2:** \( \forall s ∈ S, \phi ∈ \text{wff}. \text{FV}(\phi) ⊆ \text{dom } s \Rightarrow \vdash \phi[s] \neq \text{unknown} \)

**Proof:** By structural induction.

If \( \phi \) is \( \tau_1 \) in \( \tau_2 \) where \( \tau_1 ∈ \text{Term}_{\text{scalar}} \) and \( \tau_2 ∈ \text{Term}_s \)
  By definition of FV, FV(\( \tau_1 \)) ⊆ FV(\( \phi \)) and FV(\( \tau_2 \)) ⊆ FV(\( \phi \))
  Therefore, FV(\( \tau_1 \)) ⊆ dom s and FV(\( \tau_2 \)) ⊆ dom s
  Therefore, by Theorem 1, \( \overline{s}(\tau_1) \neq \text{unknown} \) and \( \overline{s}(\tau_2) \neq \text{unknown} \)
  By definition of \( \vdash \), \( \vdash \phi[s] \neq \text{unknown} \)

If \( \phi \) is \( (\phi_1 \text{ and } \phi_2) \) where \( \phi_1, \phi_2 \in \text{Wff} \)
  By definition of FV, FV(\( \phi_1 \)) ⊆ FV(\( \phi \)) and FV(\( \phi_2 \)) ⊆ FV(\( \phi \))
  Therefore, FV(\( \phi_1 \)) ⊆ dom s and FV(\( \phi_2 \)) ⊆ dom s
  Therefore, by induction, \( \vdash \phi_1[s] \neq \text{unknown} \) and \( \vdash \phi_2[s] \neq \text{unknown} \)
  By definition of \( \vdash \), \( \vdash \phi[s] \neq \text{unknown} \)

Other productions follow similarly

Some formulae are logically implied by other formulae. The notation \( \phi \vdash \phi' \) indicates that \( \phi \)
logically implies \( \phi' \).

**Definition 18:** \( \phi \vdash \phi' \) iff \( \forall s ∈ S_N. \vdash \phi[s] = \text{true} ⇒ \vdash \phi'[s] = \text{true} \)

Given the formula \( \phi \) used in the preceding example, \( \phi \vdash a \) in *used*.

**2.5 Generators**

The key to any generate-and-test search is the ability to generate assignments. A special function,
called a generator, generates assignments for level \( i \) of the search tree given an assignment from
level \( i-1 \). A generator for level \( i \) adds a value for the \( i^{th} \) variable to the initial assignment, without
changing the mapping of any other variable in that assignment.

**Definition 19:** \( ^4 \) A function \( g_i : S_{i-1} → \mathcal{P}S_i \) is a generator for level \( i \) of the search iff
\( \forall s ∈ S_{i-1}, \forall s' ∈ g_i(s). \forall \text{Var}_{i-1} \in s' \downarrow s' = s \)
A generator function expands a single assignment in the search tree into the complete set of assignments descending immediately from that value.

An aggregate generator can also be defined for any generator. An aggregate generator generates a complete level in the search tree, given the prior level of the search tree.

**Definition 20:** A function $G_i : \mathcal{PS}_{i-1} \rightarrow \mathcal{PS}_i$ is an aggregate generator for a level $i$ generator $g_i$ iff
$$ \forall q_{i-1} \subseteq s_{i-1}. \ G_i(q_{i-1}) = \bigcup_{q \in Q_{i-1}} g_i(q) $$

A trivial generator, corresponding to an exhaustive-enumeration search, can be associated with any variable using the exhaustive-enumeration generator $g_0$.

**Definition 21:** The exhaustive-enumeration generator $g_0$ for level $i$ is defined as
- if $v_i \in \text{Var}_{\text{scalar}}$
  $$g_0(s) = \{ s' \mid \exists x \in \text{Value}_{\text{scalar}}. \ s' = s \cup \{ v_i \mapsto x \} \}$$
- if $v_i \in \text{Var}_{\text{set}}$
  $$g_0(s) = \{ s' \mid \exists x \in \text{Value}_{\text{set}}. \ s' = s \cup \{ v_i \mapsto x \} \}$$
- if $v_i \in \text{Var}_{\text{rel}}$
  $$g_0(s) = \{ s' \mid \exists x \in \text{Value}_{\text{rel}}. \ s' = s \cup \{ v_i \mapsto x \} \}$$

A search requires a collection of generators, one associated with each variable. A function mapping each variable to an appropriate generator is called a generator suite.

**Definition 22:** A function $\gamma : \text{Variable} \rightarrow (S \rightarrow \mathcal{PS})$ is a generator suite iff
$$ \forall v \in \text{Variable}. \ \text{Ord}(v) = i \Rightarrow \gamma(v) \text{ is a generator for level } i. $$

### 2.6 Duplications

The essence of selective enumeration is reducing the number of cases generated by removing duplicates. A duplication partitions the set of full assignments into equivalence classes for some particular formula $\phi$. The only requirement for these equivalence classes is that all assignments in any equivalence class give the same interpretation to $\phi$.

**Definition 23:** A set of sets $d(\phi) : \mathcal{PS}_N$ is a duplication for the formula $\phi$ iff
- $d(\phi)$ is a partitioning of $S_N$ and
- for the equivalence relation $\approx_{d(\phi)}$ induced by $d(\phi)$, $\forall s, s' \in S_N. s \approx_{d(\phi)} s' \Rightarrow \models [s] = \models [s']$

Two obvious duplications are uninteresting for the purposes of selective enumeration. The first, which I call $d_0$, places each assignment in its own equivalence class. This corresponds to the exhaustive-enumeration search. The second obvious duplication, which I call $d_i$, divides the

---

4. I use the domain restriction operator $<_i$ from $Z$ here as well as in later definitions and theorems. For those readers unfamiliar with $Z$, the $<_i$ operator yields the relation that is the subset of the second operand restricted to those pairs whose first element is a member of the first operand. More precisely, $s <_i r = \{ (x, y) \mid (x, y) \in r \land x \in s \}$. In practice, this is used to select a subset of a relation that is meaningful for a more restricted domain.
assignments into two classes, ones that satisfy $\phi$ and ones that do not satisfy $\phi$. Although this would be the ideal duplication, it is not directly computable and therefore of no great benefit.

These two duplications can be defined in terms of the corresponding equivalence relations.

$$\forall s, s' \in S_N. \ s \approx_0 s' \iff s = s'$$

$$\forall s, s' \in S_N. \ s \approx_1 s' \iff \models_s [s] = \models_s [s']$$

The duplications described in the previous section for solving uniqueAddrAlloc can also be defined in this manner. For the reduction involving $a$ in used, every assignment for which $a$ was not an element of used was placed into a single equivalence class, with each other assignment defining its own equivalence class.

$$\forall s, s' \in S_N. \ s \approx_{a \text{ in used}} s' \iff$$

$$((\models_a \text{ in used}[s] = \text{false} \land \models_a \text{ in used}[s'] = \text{false}) \lor s = s')$$

Other bounded generation duplications, such as the constraint on usage and usage', behave similarly. Each duplication groups known false assignments together in a single equivalence class, placing all other assignment into individual equivalence classes.

This form of equivalence relation can be generalized to support any partial assignment duplication. Each partial assignment duplication has a related formula $\phi'$ that is implied by the target formula itself. It is convenient to define a special notation to describe partial assignment duplications.

**Definition 24:** An equivalence relation $\approx_{PAD(\phi, \phi')}_{PAD(\phi, \phi')}$ is a partial assignment duplicate equivalence relation iff $\phi \models \phi' \land \forall s, s' \in S_N. s \approx_{PAD(\phi, \phi')_{PAD(\phi, \phi')}} s' \iff (s = s' \lor (\models_s [s] = \text{false} \land \models_s [s'] = \text{false}))$

This places all assignments that fail to satisfy $\phi'$ into a single equivalence class and each assignment that satisfies $\phi'$ into its own equivalence class.

**Theorem 3:** The partitioning of $S_N$ induced by a partial assignment duplicate equivalence relation $\approx_{PAD(\phi, \phi')}$ is a duplication for $\phi$.

**Proof:** To prove that $\approx_{PAD(\phi, \phi')}$ induces a duplication, it is necessary to prove that

$$\forall \phi \text{Wff}. \forall s, s' \in S_N. s \approx_{PAD(\phi, \phi')} s' \Rightarrow \models_s [s] = \models_s [s']$$

By the definition of $\approx_{PAD(\phi, \phi')}$, there are two cases to consider:

- $s = s'$ and $(\models_s [s] = \text{false} \land \models_s [s'] = \text{false})$

  For the first case, clearly $\models_s [s] = \models_s [s']$.

- For the second case, if $s \in S_N$, $\models_s [s]$ is either true or false by Theorem 2. Because $\phi \models \phi'$, $\models_s [s] = \text{true} \Rightarrow \models_s [s] = \text{true}$.

  Therefore, if $\models_s [s] = \text{false}$, $\models_s [s] = \text{false}$.

  Therefore, for the second case, $\models_s [s] = \text{false} \land \models_s [s'] = \text{false}$.

**Definition 25:** $PAD(\phi, \phi')$ is the partial assignment duplication induced by the partial assignment equivalence relation $\approx_{PAD(\phi, \phi')}$. 

I will not describe the permutation duplications until I formalize the notion of permutations in Section 4.

Duplications may also be combined, further reducing the number of assignments that selective enumeration must generate and test. To combine two duplications, the corresponding equivalence relations are combined.

**Definition 26:** \( \approx_a = \approx_b \circ \approx_c \) iff
\[
\forall s, s' \in S_N. s \approx_a s' \iff ( s \approx_b s' \lor s \approx_c s' \lor ( \exists s'' \in S_N. (s \approx_{\approx_a s'' \lor s'' \approx_a s') ) )
\]

The result of combining two equivalence relations is itself an equivalence relation that induces a duplication.

**Lemma 4:** For any two equivalence relations \( \approx_b \) and \( \approx_c \), \( \approx_b \circ \approx_c \) is an equivalence relation.

**Proof:** A relation must be reflexive, symmetric and transitive to be an equivalence relation.

As \( \approx_b \) is reflexive, \( \forall s \in S_N. s \approx_b s \).
Therefore, \( \forall s \in S_N. s \approx_{\approx_b \circ \approx_c} s \).

If \( s \approx_{\approx_b \circ \approx_c} s' \), then either \( s \approx_b s' \) or \( s \approx_c s' \).
Assuming \( s \approx_b s' \), then by symmetry of \( \approx_b \), \( s' \approx_b s \).
Therefore \( s' \approx_{\approx_b \circ \approx_c} s \) and \( \approx_b \circ \approx_c \) is symmetric.

By the definition of \( \approx_b \circ \approx_c \),
\[
\forall s, s', s'' \in S_N. s \approx_{\approx_b \circ \approx_c} s' \land s' \approx_{\approx_b \circ \approx_c} s'' \Rightarrow s \approx_{\approx_b \circ \approx_c} s''.
\]

**Definition 27:** \( d_b(\phi) \circ d_c(\phi) \) is the partitioning induced by \( \approx_b \circ \approx_c \)

**Theorem 5:** \( d_b(\phi) \circ d_c(\phi) \) is a duplication.

**Proof:** Let \( d_a(\phi) = d_b(\phi) \circ d_c(\phi) \) and \( \approx_a = \approx_b \circ \approx_c \).

There are two requirements for \( d_a(\phi) \) to be a duplication:
it must be a partitioning of \( S_N \) and
\[
\forall \phi \in Wff, \forall s, s' \in S_N. s \approx_a s' \Rightarrow \phi[s] = \phi[s'].
\]

By Lemma 4, \( \approx_a \) is an equivalence relation on \( S_N \),
therefore \( d_a(\phi) \) is a partitioning of \( S_N \).

Assume \( s, s' \in S_N \) such that \( s \approx_a s' \)
By definition, one of
\[
s \approx_b s'
\]
\[
s \approx_c s'
\]
\[
\exists s'' \in S_N. (s \approx_a s'' \land s'' \approx_a s')
\]
must hold.

If either of the first two possibilities hold
then \( \phi[s] = \phi[s'] \) by definition of \( d_b(\phi) \) or \( d_c(\phi) \), respectively.
The third possibility requires the existence of a sequence of full assignments,
\( s^1, s^2, ..., s^k, s \in S_N, s \approx^1 s^1 \land s^2 \approx^2 s^2 \land s^3 \approx^3 s^3 \land ... \land s^{k-1} \approx^k s^k \land s^k \approx^{k+1} s' \)
where \( \approx^1, \approx^2, ..., \approx^k, \approx^{k+1} \) are either \( \approx_b \) or \( \approx_c \).

It is obvious by induction that such a sequence must guarantee that \( \models \phi[s] = \models \phi[s'] \).

Combining two partial assignment duplications in this manner gives the same result as the partial assignment duplication defined by the formula built from the conjunction of the two formulae defining the original duplications.

**Theorem 6:** \( \text{PAd}(\phi, \phi_1') \circ \text{PAd}(\phi, \phi_2') = \text{PAd}(\phi, (\phi_1' \land \phi_2')) \).

**Proof:** There are two distinct requirements that must be demonstrated equivalent for this theorem to hold.

The first is straightforward:
\[
\phi \models \phi_1' \land \phi \models \phi_2' \iff \phi \models (\phi_1' \land \phi_2')
\]

Let \( \approx_1 \) be the equivalence relation induced by \( \text{PAd}(\phi, \phi_1') \),
\( \approx_2 \) be the equivalence relation induced by \( \text{PAd}(\phi, \phi_2') \) and
\( \approx_{\text{and}} \) be the equivalence relation induced by \( \text{PAd}(\phi, (\phi_1' \land \phi_2')) \)

The second requirement is that
\[
( s \approx_1 s' \lor s \approx_2 s' ) \Rightarrow s \approx_{\text{and}} s' \\
( \exists s'' \in S_N. (s \approx_{\text{and}} s'' \land s'' \approx_{\text{and}} s') ) \Rightarrow s \approx_{\text{and}} s'.
\]

The second clause of this requirement is a direct consequence of the fact that \( \approx_{\text{and}} \) is an equivalence relation.

For the first clause, if \( s = s' \), then \( s \approx_1 s', s \approx_2 s' \), and \( s \approx_{\text{and}} s' \).

Otherwise, if \( s \approx_1 s' \), then \( \models \phi_1'[s] = \text{false} \land \models \phi_1'[s'] = \text{false} \).

Therefore, then \( \models (\phi_1' \land \phi_2')[s] = \text{false} \land \models (\phi_1' \land \phi_2')[s'] = \text{false} \)
Therefore, \( s \approx_{\text{and}} s' \).

Similarly, if \( s \approx_2 s' \), then \( s \approx_{\text{and}} s' \).

2.7 Soundness

It is now possible to define a selective enumeration search precisely.

**Definition 28:** A function \( \omega : \text{Wff} \times \text{Generatorsuite} \rightarrow \mathbb{P}S_N \) is a search iff
\[
\omega(\phi, \gamma) = \{ s | \models [\phi[s] = \text{true} \land s \in G_{N-1}(G_{N-2}(...G_2(G_1(\{2\})))) \}
\]
where \( G_i \) is the aggregate generator for each \( g_i \) in \( \gamma \).

To be sound, a search must guarantee that it will find at least one satisfying assignment if any exist.

**Definition 29:** A search \( \omega(\phi, \gamma) \) is sound iff \( (\exists s \in S_N. \models [\phi[s] = \text{true}] \Rightarrow \omega(\phi, \gamma) \neq \emptyset \).
For any duplication $d(\phi)$ for a formula $\phi$, selective enumeration will be sound if it enumerates at least one assignment from each satisfying set in $d(\phi)$. A generator is sound if the only satisfying assignments excluded are duplicates of other assignments generated.

**Definition 30:** A level $i$ generator $g_i$ is sound for a duplication $d(\phi)$ iff
$$\forall s \in S_N, \vdash \phi[s] = \text{true} \Rightarrow \exists s' \in S_N, \text{Var}_i \lhd s' \in g_i(\text{Var}_{i-1} \lhd s) \land s \approx_{d(\phi)} s'.$$

A subset of $S_N$ is said to represent $d(\phi)$ if it includes at least one assignment from each satisfying set in $d(\phi)$. This can be easily extended to include subsets of $S_i$ that can be used to generate a representative set.

**Definition 31:** A set $Q_i \subseteq S_i$ represents $d(\phi)$ iff
$$\forall s \in S_N, (\vdash \phi[s] = \text{true} \Rightarrow \exists s' \in S_N, (s \approx_{d(\phi)} s' \land \text{Var}_i \lhd s' \in Q_i)).$$

As a base case, the set containing only the empty assignment represents any duplication.

**Lemma 7:** $\{ \varnothing \} \subseteq S_0$ represents any $d(\phi)$.

**Proof:** Proof by construction.

By definition, $\text{Var}_0 = \varnothing$.

Therefore, $\forall s \in S_N, \text{Var}_0 \lhd s = \varnothing$.

Starting with a representative set, a sound generator will generate a representative set.

**Theorem 8:** If a level $i$ generator $g_i$ with the aggregate generator $G_i$ is sound for $d(\phi)$ then
$$\forall Q_{i-1} \subseteq S_{i-1}, Q_{i-1} \text{ represents } d(\phi) \Rightarrow G_i(Q_{i-1}) \text{ represents } d(\phi).$$

**Proof:** By contradiction.

Assume $s \in S_N, \vdash \phi[s] = \text{true} \land \forall s' \in S_N, (s \approx_{d(\phi)} s' \Rightarrow \text{Var}_i \lhd s' \in G_i(Q_{i-1})).$

By definition of represents,
$$\exists s'' \in S_N, (s \approx_{d(\phi)} s'' \land \text{Var}_i \lhd s'' \in Q_{i-1})).$$

Because $\vdash \phi[s] = \text{true}$ and $g_i$ is sound for $d(\phi)$,
$$\exists s''' \in S_N, (s'' \approx_{d(\phi)} s''' \land \text{Var}_i \lhd s''' \in G_i(Q_{i-1})).$$

By transitivity, $s \approx_{d(\phi)} s'''$.

Therefore, the assumption is contradicted.

A combination of duplications defines a new collection of equivalence classes that completely includes all of the original equivalence classes. Therefore, a generator that is sound for one duplication is also sound for that duplication in combination with any other duplication.

**Theorem 9:** If a level $i$ generator $g_i$ is sound for any duplication $d_1(\phi)$, for any duplication $d_2(\phi)$, $g_i$ is sound for $d_1(\phi) \circ d_2(\phi)$.

**Proof:** Let $s \in S_N, \vdash \phi[s] = \text{true}$,

$\approx_1$ be the equivalence relation induced by $d_1(\phi)$,
\[ =_{1\circ 2} \] be the equivalence relation induced by \( d_1(\phi) \circ d_2(\phi) \).

By the definition of a sound generator,
\[
\exists s' \in S_N. \text{Var}_1 \triangleleft s' \in g_i(\text{Var}_{i-1} \triangleleft s) \land s \approx_1 s'.
\]

By definition of \( \circ \), \( s \approx_1 s' \Rightarrow s \approx_{1\circ 2} s' \).

Therefore, \( g_i \) is sound for \( d_1(\phi) \circ d_2(\phi) \).

For a sound search, the goal is a collection of generators that can generate a representative set of full assignments.

**Lemma 10:** The result of a search \( \omega(\phi, \gamma) \) represents \( d(\phi) \) if \( \forall g_i \in \text{ran } \gamma. g_i \) is sound for \( d(\phi) \).

**Proof:** By induction on \( i \).

- Hypothesis: \( G_i(G_{i-1}(\ldots(G_1(\{\emptyset\})))) \) represents \( d(\phi) \) if \( \forall g_i \in \text{ran } \gamma. g_i \) is sound for \( d(\phi) \).

  By Lemma 7, \( \{\emptyset\} \) represents \( d(\phi) \).

  Therefore, because \( g_i \) is sound for \( d(\phi) \), \( G_1(\{\emptyset\}) \) represents \( d(\phi) \) by Theorem 8.

  By induction, \( G_{i-1}(G_{i-2}(\ldots(G_1(\{\emptyset\})))) \) represents \( d(\phi) \).

  Because \( g_i \) is sound for \( d(\phi) \),
  \[
  G_i(G_{i-1}(\ldots(G_1(\{\emptyset\})))) \text{ represents } d(\phi) \text{ by Theorem 8.}
  \]

**Theorem 11:** A search \( \omega(\phi, \gamma) \) is sound if \( \exists d(\phi). \forall g_i \in \text{ran } \gamma. g_i \) is sound for \( d(\phi) \).

**Proof:** Assume an assignment \( s \) exists such that \( \models \phi[s] = \text{true} \).

  By Lemma 10, \( \omega(\phi, \gamma) \) must represent \( d(\phi) \).

  By definition of \( \omega(\phi, \gamma) \),
  \[
  \exists q \in \omega(\phi, \gamma). \exists s' \in S_N. q = \text{Var}_1 \triangleleft s' \land s \approx_{d(\phi)} s'.
  \]

  Because \( \omega(\phi, \gamma) \subseteq S_N \) and \( \text{Var}_N \triangleleft s' = s' \), \( q = s' \).

  This implies that \( s' \in \omega(\phi, \gamma) \).
3. Bounded Generation

In the first section, I introduced bounded generation by means of a few examples. In this section, I clarify what is meant by bounded generation and prove that any bounded-generation generator is sound.

3.1 Overview of Bounded Generation

As introduced in the first section, bounded generation limits the values to be generated for any variable by limiting the underlying universe of elements. Using the claim \texttt{uniqueAddrAlloc} from Figure 1, I have demonstrated two concrete examples: constraining the value of \( a \) to be an element of the value of \texttt{used} and constraining the domain and range of the value of \texttt{usage} to be subsets of the domain and range of the value of \texttt{usage}'

The first example demonstrates a direct constraint on the universe of elements from which a scalar value is chosen. In the second example, a relation is restricted to a (generally) smaller universe of elements for the domain and the range. In each example, bounded generation uses information derived from the formula to reduce the possible values to be generated.

This reduction is the essence of bounded generation. Unlike most other techniques, bounded generation does not provide any self-contained generators. Instead, bounded generation depends on other generators, possibly even using generators implementing other reduction techniques.

Another example of bounded generation begins with the atomic formula \( \texttt{used}' = (\texttt{used} \cup \{ a \}) \) found in Formula 2. Any assignment satisfying this formula also satisfies the formula \( \texttt{used} \subseteq \texttt{used}' \). This new formula logically implies \( \texttt{used} \land (\texttt{Unused}' ) = \emptyset \).

For bounded generation of set variables, such as \texttt{used}, the goal is to divide the universe of elements \( 'U \) into three distinct subsets: elements that are required to be included in the set denoted by the variable, elements that are never in that set, and elements that may possibly (but not necessarily) be in that set. For this example, any element contained in the set given by \( S_{set}(\texttt{Unused}') \) can never be in the set denoted by \texttt{used} for any satisfying assignment. With a different value for \texttt{Ord} (generating values for \( a \) before generating values for \texttt{used}), it could also be determined that the element denoted by \( a \) is in the set denoted by \texttt{used} for any satisfying assignment. This relationship is illustrated in Figure 4.

The set of elements that may possibly be included is described by a term, which I call \( P \). For this example, \( P \) is \( (\texttt{used}' \setminus a) \). The set of elements that are required for any satisfying assignment are described by a similar term, which I call \( R \). For this example, \( R \) is \( a \). The underlying generator needs to consider only the elements contained in \( S_{set}(P) \). Bounded generation unions each value yielded by the underlying generator with the value of \( S_{set}(R) \). If the underlying generator generates each subset of \( S_{set}(P) \), bounded generation will be sound. In fact, as will be shown in the following sections, bounded generation is sound when combined with some underlying generators that do not yield all possible subsets of \( S_{set}(P) \).

For scalar variables, there is no subset of elements always included, so the value of \( R \) is always \( \emptyset \). A naive underlying generator could yield each element of \( S_{set}(P) \), which the bounded-generation generator would yield unchanged.

Relational variables are the most complicated for bounded generation. The most consistent and efficient definition of bounded generation for relations would consider sets of edges, rather than
Figure 4: Partitioning \( \mathcal{U} \) into three sets for bounded generation of \textit{used}. The first (leftmost) partition includes all elements that are required to be included in any the value of \textit{used} for any satisfying assignment. In this example, this is simply the value denoted by the variable \texttt{a}. The term \( \mathcal{R} \) is used to describe these values. The second partition includes all elements that may possibly be included in the value of \textit{used}. The term \( \mathcal{P} \) is used to describe these values. The third, and final, partition includes all elements that must not be included in the value of \textit{used}. In this example, this is the value \( \overline{\text{set}}(\ \text{\texttt{un}} \setminus \text{\textit{used}}) \). Only the elements in the middle partition need to be considered by the underlying generator.

the sets of elements used for scalar and set generation. This definition, however, significantly complicates both the definition and implementation of bounded generation. Instead, I use sets of elements for bounded generation of relations as well. One set describes the elements that may or may not be in the domain of the relation for a satisfying assignment. I call the term describing this set \( \mathcal{P} \), as with scalar or set generation. There is a similar term, which I call \( p \), that describes the set of elements that may or may not be part of the range. As with scalar generation, \( \mathcal{R} \) is uninteresting, so \( \mathcal{R} \) is always \( \{\} \).

3.2 \( \mathcal{P}p \) Limitation

Bounded generation depends on generating values from a limited universe of elements. In this section, I develop a notation for describing the underlying limitations.

These limitations are based on two elements from \( \text{Term}_{\text{set}} \), referred to as \( \mathcal{P} \) and \( p \). The currently generated partial assignment \( \mathcal{S} \) provides the context to evaluate these terms, using the \( \text{set} \) function. For scalar values and set values, only \( \mathcal{P} \) is interesting, with \( \overline{\text{set}}(\mathcal{P}) \) yielding the base set from which elements may be drawn. For relational values, \( \overline{\text{set}}(\mathcal{P}) \) limits the domain and \( \overline{\text{set}}(p) \) limits the range.

**Definition 32:** For any \( \mathcal{P}, p \in \text{Term}_{\text{set}} \), value \( x \) is \( \mathcal{P}p \)-limited for assignment \( \mathcal{S} \) iff

\[
\begin{align*}
\text{FV}(\mathcal{P}) & \subseteq \text{dom } \mathcal{S} \land \text{FV}(p) \subseteq \text{dom } \mathcal{S} \land \\
(x \in \text{Value}_{\text{scalar}} & \Rightarrow x \in \mathcal{S}(\mathcal{P})) \land \\
\end{align*}
\]

5. As will be shown in Section 6, where I refine the model to distinguish functions from general relations, a term describing a set of edges equivalent to \( \mathcal{R} \) is useful for the generation of functions.
\[(x \in \text{Value}_{\text{set}} \Rightarrow x \subseteq \bar{s}(\mathcal{P})) \land (x \in \text{Value}_{\text{rel}} \Rightarrow x \subseteq \{ (y,z) \mid y \in \bar{s}(\mathcal{P}) \land z \in \bar{s}(\mathcal{P}) \}) \]

The limit functions generate \(\mathcal{P}p\)-limited values and assignments for most values and assignments. These functions, however, cannot \(\mathcal{P}p\)-limit a scalar value that is not already \(\mathcal{P}p\)-limited, or an assignment that maps a variable to a scalar value that is not already \(\mathcal{P}p\)-limited.

**Definition 33:** For the function \(\text{limit}_{\text{pp}}: \text{Value} \times S \rightarrow \text{Value} \cup \{\text{unknown}\}, \text{limit}_{\text{pp}}(x, s)\) is
\[
\begin{align*}
\text{if } & (\text{FV}(\mathcal{P}) \subseteq \text{dom } s \land \text{FV}(p) \subseteq \text{dom } s) \\
& \text{unknown}
\end{align*}
\]
if \(x \in \text{Value}_{\text{scalar}}\)
\[
\begin{align*}
& x \\
& \text{if } x \in \bar{s}(\mathcal{P}) \\
& \text{unknown} \\
& \text{otherwise}
\end{align*}
\]
if \(x \in \text{Value}_{\text{set}}\)
\[
\{ y \mid y \in \bar{s}(\mathcal{P}) \land y \in x \}
\]
if \(x \in \text{Value}_{\text{rel}}\)
\[
\{ (y,z) \mid y \in \bar{s}(\mathcal{P}) \land z \in \bar{s}(\mathcal{P}) \land (y,z) \in x \}
\]

**Definition 34:** The function \(\text{limit}_{\text{p}}: S \rightarrow S\) is defined as
\[
\begin{align*}
\text{limit}_{\text{p}}(s) = \\
\{ v \mapsto x \mid v \in \text{dom } s \land \text{Ord}(v) \neq i \land x = s(v) \} \cup \\
\{ v \mapsto x \mid v \in \text{dom } s \land \text{Ord}(v)=i \land x = \text{limit}_{\text{pp}}(s(v), s) \}
\end{align*}
\]

For scalar variables, the function \(\text{limit}_{\text{p}}\) leaves \(v_i\) unbound in the resultant assignment if the value \(s(v)\) is not already \(\mathcal{P}p\)-limited.

A generator can be \(\mathcal{P}p\)-limiting.

**Definition 35:** For any \(\mathcal{P}, p \in \text{Term}_{\text{set}}\) such that \(\text{FV}(\mathcal{P}) \subseteq \text{Vars}_{i-1}\) and \(\text{FV}(p) \subseteq \text{Vars}_{i-1}\), a level \(i\) generator \(g_{i}^{\mathcal{P}}\) is a \(\mathcal{P}p\)-limiting generator iff \(\forall s \in \text{S}_{i-1}, \forall s' \in g_{i}^{\mathcal{P}}(s).s'(v_i)\) is \(\mathcal{P}p\)-limited for \(s\).

An exhaustive-enumeration \(\mathcal{P}p\)-limiting generator can be defined.

**Definition 36:** For some \(\mathcal{P}, p \in \text{Term}_{\text{set}}\) such that \(\text{FV}(\mathcal{P}) \subseteq \text{Vars}_{i-1}\) and \(\text{FV}(p) \subseteq \text{Vars}_{i-1}\), the level \(i\) generator \(g_{0}^{\mathcal{P}}: S_{i-1} \rightarrow \text{PS}_{i}\) is defined as
\[
\begin{align*}
\text{if } & v_i \in \text{Vars}_{\text{scalar}} \\
& g_{0}^{\mathcal{P}}(s) = \{ s' \mid \exists x \in \bar{s}(\mathcal{P}). s' = s \cup \{ v_i \mapsto x \} \}
\end{align*}
\]
\[
\begin{align*}
\text{if } & v_i \in \text{Vars}_{\text{set}} \\
& g_{0}^{\mathcal{P}}(s) = \{ s' \mid \exists x \in \text{PS}(\mathcal{P}). s' = s \cup \{ v_i \mapsto x \} \}
\end{align*}
\]
\[
\begin{align*}
\text{if } & v_i \in \text{Vars}_{\text{rel}} \\
& g_{0}^{\mathcal{P}}(s) = \{ s' \mid \exists x \in \text{PS}(\mathcal{P}) \times \bar{s}(\mathcal{P}). s' = s \cup \{ v_i \mapsto x \} \}
\end{align*}
\]

**Theorem 12:** The level \(i\) generator \(g_{0}^{\mathcal{P}}\) given by Definition 36 is a \(\mathcal{P}p\)-limiting generator.

**Proof:** Let \(\mathcal{P}, p \in \text{Term}_{\text{set}}\) such that \(\text{FV}(\mathcal{P}) \subseteq \text{Vars}_{i-1}\) and \(\text{FV}(p) \subseteq \text{Vars}_{i-1}\) and \(s \in \text{S}_{i-1}\).
if $v_i \in \text{Var}_{\text{scalar}}$

\[ \forall s' \in g0^{\phi}(s).s'(v_i) \in \overline{s}(P) \]

Therefore, $s'(v_i)$ is $Pp$-limited for $s$.

The other cases follow similarly.

Just as a set of assignments can represent a duplication, a set of assignments can be a $Pp$-limited representative of a duplication.

**Definition 37:** For any $Pp \in \text{Term}_{\text{set}}$ such that $\text{FV}(P) \subseteq \text{Var}_{i-1}$ and $\text{FV}(p) \subseteq \text{Var}_{i-1}$, a set $L_i \subseteq S_i$ is a $Pp$-limited representative of $d(\phi)$ iff

\[ \forall s \in S_i, \ \exists \phi[s] = \text{true} \Rightarrow \exists s' \in S_i, s \approx_{d(\phi)} s' \land \text{limit}^{Pp}(\text{Var}_i \triangleleft s') \in L_i. \]

This is almost the same definition as was used for represents originally. Instead of matching a partial assignment from each equivalence class in $d(\phi)$, it is now necessary to match a $Pp$-limited partial assignment from each equivalence class.

**Definition 38:** A $Pp$-limited level $i$ generator $g^P_i$ is $Pp$-limited sound for $d(\phi)$ iff

\[ \forall s \in S_i, \ \exists \phi[s] = \text{true} \Rightarrow \exists s' \in S_i, s \approx_{d(\phi)} s' \land \text{limit}^{Pp}(\text{Var}_i \triangleleft s') \in g^P_i(\text{Var}_{i-1} \triangleleft s). \]

As before, a generator is sound if it yields a value equivalent to each possible value, except it now yields the $Pp$-limited equivalent value. The aggregate generator for a $Pp$-limited sound generator yields a $Pp$-limited representative set when given a $Pp$-limited representative set.

**Theorem 13:** If a $Pp$-limited level $i$ generator $g^P_i$ with the aggregate generator $G^P_i$ is $Pp$-limited sound for $d(\phi)$ then

\[ \forall Q_{i-1} \subseteq S_{i-1}, Q_{i-1} \text{ represents } d(\phi) \Rightarrow G^P_i(Q_{i-1}) \text{ } Pp\text{-limited represents } d(\phi). \]

**Proof:** By construction.

Assume $s \in S_i, \exists \phi[s] = \text{true}.$

Because $Q_{i-1}$ represents $d(\phi),$

\[ \exists s' \in S_i, s \approx_{d(\phi)} s' \land \text{Var}_{i-1} \triangleleft s' \in Q_{i-1}. \]

Therefore, by definition of $Pp$-limited sound,

\[ \exists s'' \in S_i, \text{limit}^{Pp}(\text{Var}_{i-1} \triangleleft s'') \in g^P_i(\text{Var}_{i-1} \triangleleft s') \land s' \approx_{d(\phi)} s''. \]

By transitivity, $s \approx_{d(\phi)} s''.$

Therefore, because $\text{limit}^{Pp}(\text{Var}_{i-1} \triangleleft s'') \in G^P_i(Q_{i-1}),$

$G^P_i(Q_{i-1})$ is a $Pp$-limited representative of $d(\phi).$

The $Pp$-limited exhaustive-enumeration generator defined earlier is $Pp$-limited sound.

**Theorem 14:** The exhaustive-enumeration $Pp$-limiting generator $g0^{\phi}P$ defined by Definition 36 is a $Pp$-limited sound level $i$ generator for any duplication $d(\phi)$ and formula $\phi$ such that $v_i \in \text{Var}_{\text{scalar}} \Rightarrow \phi \land v_i \in P.$

**Proof:** There are three cases to consider based on the kind of variable.
If $v_i \in \text{Var}_{\text{scalar}}$

By definition, $\mathcal{I}[s] = \text{true} \Rightarrow s(v_i) \in \overline{s}(P)$.

By definition of $g^{\mathcal{P}}_i$,

$$\forall s \in S_N \forall x \in \overline{s}(P). \exists s' \in g^{\mathcal{P}}_i(\text{Var}_{i-1} \triangleleft s). s'(v_i) = x$$

Therefore, $\forall s \in S_N. \mathcal{I}[s] = \text{true} \Rightarrow s \in g^{\mathcal{P}}_i(\text{Var}_{i-1} \triangleleft s)$

Therefore, $\lim_{\mathcal{P}}(\text{Var}_i \triangleleft s) \in g^{\mathcal{P}}_i(\text{Var}_{i-1} \triangleleft s)$

Because $s \approx_{d(\mathcal{P})} s$ by definition, $g^{\mathcal{P}}_i$ is $\mathcal{P}$-limited sound.

If $v_i \in \text{Var}_{\text{set}}$

By definition of $\lim^{\mathcal{P}}$, $\forall s \in S_N. \forall x \in \text{Value}_{\text{set}}. \lim^{\mathcal{P}}(x, s) \subseteq \overline{s}(P)$.

Therefore, $\forall s \in S_N. \lim^{\mathcal{P}}(s(v_i), s) \subseteq \overline{s}(P)$.

By definition of $g^{\mathcal{P}}_i$, $\forall s \in S_N. \forall x \subseteq \overline{s}(P). \exists s' \in g^{\mathcal{P}}_i(s). s'(v_i) = x$

Therefore, $\forall s \in S_N. \lim^{\mathcal{P}}(\text{Var}_i \triangleleft s) \in g^{\mathcal{P}}_i(s)$.

A similar argument follows when $v_i \in \text{Var}_{\text{rel}}$.

3.3 Definition of Bounded Generation

I now define bounded generation in terms of $\mathcal{P}$-limiting.

**Definition 39**: For any $\mathcal{P}, p, R \in \text{Term}_{\text{set}}$, a level $i$ generator $bg^{\mathcal{P}R}_i$ is a bounded generator for $\phi$

using a $\mathcal{P}$-limiting generator $g^{\mathcal{P}R}_i$, iff

$$\text{FV}(P) \subseteq \text{Var}_{i-1} \land \text{FV}(p) \subseteq \text{Var}_{i-1} \land \text{FV}(R) \subseteq \text{Var}_{i-1} \land$$

(V) $v_i \in \text{Var}_{\text{scalar}} \Rightarrow$

$$\phi \equiv v_i \in P \land v_i = \{\} \land R = \{\} \land$$

$$\text{bg}^{\mathcal{P}R}_i(s) = g^{\mathcal{P}R}_i(s)$$

(V) $v_i \in \text{Var}_{\text{set}} \Rightarrow$

$$\phi \equiv v_i \subseteq (P \cup R) \land \phi \equiv R \subseteq v_i \land v_i = \{\} \land$$

$$\text{bg}^{\mathcal{P}R}_i(s) = \{s' | \exists s'' \in g^{\mathcal{P}R}_i(s). s' = s'' \cup \overline{s}(R)\}$$

(V) $v_i \in \text{Var}_{\text{rel}} \Rightarrow$

$$\phi \equiv \text{dom } v_i \subseteq P \land \phi \equiv \text{ran } v_i \subseteq P \land R = \{\} \land$$

$$\text{bg}^{\mathcal{P}R}_i(s) = g^{\mathcal{P}R}_i(s)$$

This definition exactly corresponds to the overview of bounded generation given earlier. All the terms used must be well defined for any partial assignment considered as an input. For scalar variables, the generator utilizes an underlying generator that considers only the possible values, as given by the term $P$. For set variables, the generator unions the required elements, as indicated by the $R$ term, with each value yielded by the underlying generator considering only the non-required possible elements, as given by the $P$ term. For relational variables, the generator yields values given by the underlying generator considering a reduced set of possible elements for the domain (indicated by the term $P$) and for the range (indicated by the term $p$).
A bounded-generation generator, when combined with a $\mathcal{P}p$-limited sound generator, is sound for appropriate partial assignment duplications.

**Theorem 15:** If $v_i \in \text{Var}_{\text{scalar}}$ and $g_i^{\mathcal{P}p}$ is $\mathcal{P}p$-limited sound for $\text{PAD}(\psi, v_i \in \mathcal{P})$, then the level $i$ bounded generator $bg_i^{\mathcal{P}pR}$ using the exhaustive-enumeration $\mathcal{P}p$-limiting generator $g_i^{\mathcal{P}p}$ is sound for $\text{PAD}(\psi, v_i \in \mathcal{P})$.

**Proof:**

Because $\psi v_i \in \mathcal{P}$, $\forall s \in S_{N}$. $\exists s \in S_{N}$. $s \models \phi$. $s(v) = \text{true} \Rightarrow s(v_i) \in \overline{S}(\mathcal{P})$

By definition, $s(v) \in \overline{S}(\mathcal{P}) \Rightarrow \text{limit}_{i}^{\mathcal{P}p}(s(v)) = s(v_i)$

Therefore, $\forall s \in S_{N}$. $s \models \phi$. $s \Rightarrow \text{limit}_{i}^{\mathcal{P}p}(\text{Var}_{i} \triangleleft s) = \text{Var}_{i} \triangleleft s$.

Therefore, $g_i^{\mathcal{P}p}$ is sound for $\text{PAD}(\phi, v_i \in \mathcal{P})$.

Because $bg_i^{\mathcal{P}pR} = g_i^{\mathcal{P}p}$ when $v_i \in \text{Var}_{\text{scalar}}$, $bg_i^{\mathcal{P}pR}$ is sound for $\text{PAD}(\phi, v_i \in \mathcal{P})$.

**Theorem 16:** If $v_i \in \text{Var}_{\text{set}}$ and $g_i^{\mathcal{P}p}$ is $\mathcal{P}p$-limited sound for $\text{PAD}(\phi, (v_i \in (\mathcal{P} \cup \mathcal{R}) \text{ and } \mathcal{R} \in v_i))$, then the level $i$ bounded generator $bg_i^{\mathcal{P}pR}$ using the exhaustive-enumeration $\mathcal{P}p$-limiting generator $g_i^{\mathcal{P}p}$ is sound for $\text{PAD}(\phi, (v_i \in (\mathcal{P} \cup \mathcal{R}) \text{ and } \mathcal{R} \in v_i))$.

**Proof:** By construction.

Let $s \in S_{N}$. $s \models \phi$. $s \Rightarrow s = \text{PAD}(s \wedge \text{limit}_{i}^{\mathcal{P}p}(\text{Var}_{i} \triangleleft s) \in g_i^{\mathcal{P}p}(\text{Var}_{i} \triangleleft s))$.

By the definition of $=_{\text{PAD}}$ and because $s \models \phi$. $s = \text{PAD}(s \wedge \text{limit}_{i}^{\mathcal{P}p}(\text{Var}_{i} \triangleleft s) \in g_i^{\mathcal{P}p}(\text{Var}_{i} \triangleleft s))$.

By definition, $\text{limit}_{i}^{\mathcal{P}p}(\text{Var}_{i} \triangleleft s)(v_i) = s(v_i) \cap \overline{S}(\mathcal{P})$.

Because $\phi(v_i \in (\mathcal{P} \cup \mathcal{R}) \text{ and } \mathcal{R} \in v_i)$,

Therefore, $\phi v_i \in (\mathcal{P} \cup \mathcal{R}) \wedge s \models \phi \Rightarrow s = s_i$.

Therefore, $s(v) \subseteq \overline{S}(\mathcal{P}) \cup \overline{S}(\mathcal{R})$.

Therefore, $s(v) \subseteq (s(v) \cap \overline{S}(\mathcal{P})) \cup \overline{S}(\mathcal{R})$.

Because $\overline{S}(\mathcal{R}) \subseteq s(v)$, $(s(v) \cap \overline{S}(\mathcal{P})) \cup \overline{S}(\mathcal{R}) \subseteq s(v)$.

Therefore, $(s(v) \cap \overline{S}(\mathcal{P})) \cup \overline{S}(\mathcal{R}) = s(v)$.

Therefore, $\text{limit}_{i}^{\mathcal{P}p}(\text{Var}_{i} \triangleleft s)(v_i) \cup \overline{S}(\mathcal{R}) = s(v_i)$.

Therefore $s \in bg_i^{\mathcal{P}pR}(\text{Var}_{i} \triangleleft s)$.

**Theorem 17:** If $v_i \in \text{Var}_{\text{rel}}$ and $g_i^{\mathcal{P}p}$ is $\mathcal{P}p$-limited sound for $\text{PAD}(\phi, (\text{dom } v_i \in \mathcal{P} \text{ and ran } v_i \in \mathcal{P})$, then the level $i$ bounded generator $bg_i^{\mathcal{P}pR}$ using the exhaustive-enumeration $\mathcal{P}p$-limit-
ing generator $g_i^{P_i}$ is sound for $PAd(\phi_i(\text{dom } v_i \leq P \text{ and ran } v_i \leq p))$.

**Proof:** By a similar argument used in the proof for Theorem 16.
4. Isomorph Elimination

This section begins by providing an overview of isomorph elimination. The second subsection defines permutation duplicates based on automorphisms on $\mathcal{U}$, the universe of atomic elements. Using the definition of the formula language, I show that applying an automorphism function to all of the values in the range of an assignment does not change the interpretation of the formula for the modified assignment. I define isomorph elimination in terms of these automorphisms. From this, I show that isomorph-eliminating generators are sound.

In the final subsection, I show that an isomorph-eliminating generator can be used as the underlying $\mathcal{Fp}$-limiting generator for sound bounded generation.

4.1 Overview of Isomorph Elimination

Conceptually, isomorph elimination is a direct outgrowth of a simple observation: two isomorphic assignments will give the same interpretation to any formula. Two assignments are isomorphic if there is a consistent shuffling of the elements in one assignment, called a relabeling, that yields the second assignment. As the elements of $\mathcal{U}$ are unstructured, no two elements are distinguishable, except through prior usage. Therefore, a relabeled assignment must give the same interpretation to a formula as the original assignment.

Because of the incremental approach taken in selective enumeration, an isomorph-eliminating generator considers only relabellings that do not effect the partial assignment already computed. For an initial partial assignment, an isomorph-eliminating generator can safely exclude any value for the new variable that is a relabeling of another value that is generated if that relabeling leaves the initial partial assignment unchanged. In this way, the values already generated in earlier levels limit the possible relabellings to consider in this new level.

Ideally, the generator would guarantee that no assignments generated for a given level of the search tree would be isomorphic to each other. However, there are two difficulties in achieving complete isomorph elimination. As the generator considers only a single partial assignment from the previous level at a time, it cannot guarantee that two assignments generated from two different initial partial assignments are not isomorphic. Secondly, perfect recognition of isomorphs is itself non-polynomial, so acceptable performance requires the use of a heuristic.

Basic isomorph elimination is dependent solely on the formula language, rather than on the actual formula being analyzed, as is bounded generation. Although further reductions can be gained by considering the formula [JJD98], I ignore those considerations in this analysis.

4.2 Automorphisms

An automorphism is a function that performs a consistent relabeling of a value or an assignment.

**Definition 40:** A one-to-one function $\hat{h} : \text{Value} \rightarrow \text{Value}$ is an automorphism for $\mathcal{U}$ iff
\[
\forall y \in \text{Value}_{\text{set}}. \forall x \in \text{Value}_{\text{scalar}}. x \in y \Leftrightarrow \hat{h}(x) \in \hat{h}(y) \land \\
\forall z \in \text{Value}_{\text{rel}}. \forall x, x' \in \text{Value}_{\text{scalar}}. x' \in z(x) \Leftrightarrow \hat{h}(x') \in \hat{h}(z)(\hat{h}(x))
\]

**Definition 41:** For any automorphism $\hat{h}$, $\hat{h}(s) = \{ v \rightarrow x \mid v \in \text{dom} \ s \land x = \hat{h}(s(v)) \}$. Furthermore, $\hat{h}(s)$ is the semantic function induced by $\hat{h}(s)$.
Because all of the elements of $\mathcal{U}$ are unstructured, applying any automorphism to an assignment does not change the meaning of that assignment for any terms or formulae.

**Lemma 18:** For any automorphism $\widehat{h}$, term $\tau$, and assignment $s$, 
\[ \overline{s}(\tau) \neq \text{unknown} \Rightarrow \widehat{h}(\overline{s}(\tau)) = \widehat{h}(s)(\tau). \]

**Proof:** By structural induction on the definition of $\overline{s}(\tau)$.

If $\tau$ is $v$ where $v \in \text{Variable}$

By definition of $\overline{s}$, $\overline{s}(\tau) = s(v)$.

By definition of $\widehat{h}(\overline{s})$, $\widehat{h}(\overline{s})(\tau) = \widehat{h}(s(v))$.

If $\tau$ is $(\tau_1 \cup \tau_2)$ where $\tau_1, \tau_2 \in \text{Term}_{\text{set}}$

Because $\overline{s}(\tau) \neq \text{unknown}$, $\overline{s}(\tau_1) \neq \text{unknown}$ and $\overline{s}(\tau_2) \neq \text{unknown}$.

By induction, $\widehat{h}(\overline{s}(\tau_1)) = \widehat{h}(s)(\tau_1)$ and $\widehat{h}(\overline{s}(\tau_2)) = \widehat{h}(s)(\tau_2)$.

Therefore, by definition of $\overline{s}$, $\widehat{h}(\overline{s}(\tau)) = \widehat{h}(s)(\tau)$

Other productions follow similarly.

**Theorem 19:** For any automorphism $\widehat{h}$, formula $\phi$, and assignment $s$,
\[ \vdash \phi[s] \neq \text{unknown} \Rightarrow \vdash \phi[s] = \vdash \phi[\widehat{h}(s)]. \]

**Proof:** By Lemma 18 and structural induction on the definition of the formula language.

If $\phi$ is $\tau_1$ in $\tau_2$ where $\tau_1 \in \text{Term}_{\text{scalar}}$ and $\tau_2 \in \text{Term}_{\text{set}}$

Because $\vdash \phi[s] \neq \text{unknown}$, $\overline{s}(\tau_1) \neq \text{unknown}$ and $\overline{s}(\tau_2) \neq \text{unknown}$.

By definition of $\vdash$, if $\vdash \phi[s] = \text{true}$, $\overline{s}(\tau_1) \in \overline{s}(\tau_2)$.

Therefore, by Definition 41, $\widehat{h}(\overline{s}(\tau_1)) \in \widehat{h}(\overline{s}(\tau_2))$.

Therefore, by Lemma 18, $\widehat{h}(\overline{s})(\tau_1) \in \widehat{h}(\overline{s})(\tau_2)$.

Therefore, $\vdash \phi[\widehat{h}(s)] = \text{true}$

By definition of $\vdash$, if $\vdash \phi[s] = \text{false}$, $\overline{s}(\tau_1) \notin \overline{s}(\tau_2)$.

Therefore, by Definition 41, $\widehat{h}(\overline{s}(\tau_1)) \notin \widehat{h}(\overline{s}(\tau_2))$.

Therefore, by Lemma 18, $\widehat{h}(\overline{s})(\tau_1) \notin \widehat{h}(\overline{s})(\tau_2)$.

Therefore, $\vdash \phi[\widehat{h}(s)] = \text{false}$

If $\phi$ is $(\phi_1$ and $\phi_2$) where $\phi_1, \phi_2 \in \text{Wff}$

If $\vdash \phi_1[s] = \text{true}$, $\vdash \phi_1[\overline{h}(s)] = \text{true}$ by induction

If $\vdash \phi_2[s] = \text{true}$, $\vdash \phi_2[\overline{h}(s)] = \text{true}$ by induction

Therefore, by definition of $\vdash$, if $\vdash \phi[s] = \text{true}$, $\vdash \phi[\overline{h}(s)] = \text{true}$

If $\vdash \phi_1[s] = \text{false}$, $\vdash \phi_1[\overline{h}(s)] = \text{false}$ by induction

If $\vdash \phi_2[s] = \text{false}$, $\vdash \phi_2[\overline{h}(s)] = \text{false}$ by induction

Therefore, by definition of $\vdash$, if $\vdash \phi[s] = \text{false}$, $\vdash \phi[\overline{h}(s)] = \text{false}$

Other productions follow similarly.

An isomorph-eliminating generator considers only automorphisms that leave the initial partial assignment unchanged. These automorphisms are called identities.
**Definition 42:** An automorphism $\hat{h}$ is an identity for an assignment $s$ iff $s = \hat{h}(s)$

For any empty assignment or an assignment containing only empty sets and empty relations, any automorphism is an identity. For the assignment considered earlier

$$\{ \text{usage}^v \mapsto \{ (a_0, v_0) \}, \text{used}^v \mapsto \emptyset \}$$

any automorphism that maps $a_0$ to $a_0$ and $v_0$ to $v_0$ is an identity.

Identities for the more complicated assignment

$$\{ \text{usage}^v \mapsto \{ (a_0, v_0), (a_1, v_0) \}, \text{used}^v \mapsto \{ a_0, a_1 \} \}$$

include automorphisms that map $a_0$ to $a_1$, $a_1$ to $a_0$, and $v_0$ to $v_0$ as well as the expected automorphisms that map $a_0$ to $a_0$, $a_1$ to $a_1$, and $v_0$ to $v_0$.

If an automorphism is an identity over a partial assignment, it is an identity for any value obtained by evaluating a term using that assignment.

**Lemma 20:** If $\hat{h}$ is an automorphism that is an identity for a partial assignment $s \in S_i$ and $\tau \in \text{Term}$ such that $\text{FV}(\tau) \subseteq \text{Var}_i$, then $\hat{h}(\overline{s}(\tau)) = \overline{s}(\tau)$.

**Proof:** By structural induction on term language.

- By Theorem 1, $\overline{s}(\tau) \neq \text{unknown}$.

- If $\tau$ is $v$, where $v \in \text{Variable}$
  - $\overline{s}(\tau) = s(\tau)$ by definition
  - Because $\hat{h}$ is an identity for $s$, $\hat{h}(\overline{s}(\tau)) = s(\tau)$

- If $\tau$ is $(\tau_1 \cup \tau_2)$, where $\tau_1, \tau_2 \in \text{Term}_{\text{set}}$
  - By induction, $\hat{h}(\overline{s}(\tau_1)) = \overline{s}(\tau_1)$ and $\hat{h}(\overline{s}(\tau_2)) = \overline{s}(\tau_2)$
  - Therefore, $\hat{h}(\overline{s}(\tau)) = s(\tau)$

Other productions follow similarly. 

**4.3 Definition of Isomorph Elimination**

To define isomorph elimination precisely, it is useful to start with a definition of the duplication being reduced by the generator. The duplication places any two assignments in the same equivalence class if they are isomorphic to each other.

**Definition 43:** An equivalence relation $\approx_{\pi}$ is a permutation equivalence relation iff

$$\forall s, s' \in S_N, s \approx_{\pi} s' \iff (\exists \hat{h}. \hat{h} \text{ is an automorphism function and } s' = \hat{h}(s))$$

**Lemma 21:** The partitioning defined by $\approx_{\pi}$ is a duplication.

**Proof:** By Theorem 19.

**Definition 44:** $\pi d(\emptyset)$ is the duplication induced by $\approx_{\pi}$.

The goal of an isomorph-eliminating generator is to generate only assignments that are not isomorphs of other assignments generated.
Definition 45: A level $i$ generator $g_i$ is an isomorph-eliminating generator iff
\[ \forall s \in S_{i-1}. \forall x \in \text{Value}. \exists s' \in g_i(s). \]
\[ (\exists h. h \text{ is an automorphism } \land h \text{ is an identity for } s \land s'(v_i) = h(x)) \]

An isomorph-eliminating generator is any generator that is guaranteed to generate at least any value for this level that is not isomorphic to another value also generated. As was noted earlier, it is not realistic to require an isomorph-eliminating generator to remove all isomorphs. As such, the exhaustive-enumeration generator given in Definition 21 is a valid isomorph-eliminating generator, albeit an extraordinarily inefficient one. In practice, a middle ground is available; an efficient generator that eliminates almost all isomorphs can be implemented with reasonable effort.

Because an isomorph-eliminating generator only drops an assignment if there is an automorphism that relabels that assignment into one that is generated, there is at least one element generated for each equivalence class in $\pi_d(\phi)$.

Theorem 22: An isomorph-eliminating generator $g_i$ is sound for $\pi_d(\phi)$.

Proof: Assume $s \in S_N. k[\phi] = \text{true}$.

Let $x = s(v_i)$.

By definition of an isomorph-eliminating generator,
\[ \exists s' \in g_i(\forall X \land X. \triangleleft s). \]
\[ (\exists h. h \text{ is an automorphism } \land h \text{ is an identity for } s \land s'(v_i) = h(x)) \]

Therefore, $h(s) = s'$.

Therefore, $s \approx \pi s'$.

4.4 Interaction of Isomorph Elimination and Bounded Generation

To minimize the number of assignments generated, selective enumeration utilizes all the duplications available. As shown in Theorem 6, different partial assignment duplications combine to reduce the number of assignments for a single formula in a straightforward manner. The complexity comes when combining a partial assignment duplication with a permutation duplication: $\text{PAD}(\phi, \phi') \circ \pi_d(\phi)$.

If the partial assignment duplication enables a derived variable, only one assignment will be generated and combination with isomorph elimination is unnecessary. Short circuiting, as described in the next section, is really more of a post-filter than a generator and combines with any other generators in a straightforward manner. The issue is therefore limited to combining isomorph-eliminating generators with bounded-generation generators. The approach is to utilize an isomorph-eliminating generator as the underlying generator for a bounded-generation generator.

This requires a $\mathcal{P}$-limiting version of an isomorph-eliminating generator to be defined.

Definition 46: For $\mathcal{P}, p \in \text{Term}_{set}$ such that $\text{FV}(\mathcal{P}) \subseteq \text{Var}_{i-1}$ and $\text{FV}(p) \subseteq \text{Var}_{i-1}$, a level $i$ generator $g_{i, \mathcal{P}}$ is a $\mathcal{P}$-isomorph-eliminating generator for formula $\phi$ iff
\[ V_i \in \text{Var}_{\text{scalar}} \Rightarrow \forall S \in S_{i-1}. \forall x \in \text{Value}_{\text{scalar}}. \]
\[ (x \in \overline{S}(P)) \lor \]
\[ \exists s' \in g_i(s). \]
\[ (\exists h, \overline{h} \text{ is an automorphism } \land \]
\[ \overline{h} \text{ is an identity for } S \land \]
\[ s'(v_i) = \overline{h}(\lim_{P}(x, S)) \land \]

\[ V_i \in \text{Var}_{\text{set}} \Rightarrow \forall S \in S_{i-1}. \forall x \in \text{Value}_{\text{set}}. \]
\[ \exists s' \in g_i(s). \]
\[ (\exists h, \overline{h} \text{ is an automorphism } \land \]
\[ \overline{h} \text{ is an identity for } S \land \]
\[ s'(v_i) = \overline{h}(\lim_{P}(x, S)) \land \]

\[ V_i \in \text{Var}_{\text{rel}} \Rightarrow \forall S \in S_{i-1}. \forall x \in \text{Value}_{\text{rel}}. \]
\[ \exists s' \in g_i(s). \]
\[ (\exists h, \overline{h} \text{ is an automorphism } \land \]
\[ \overline{h} \text{ is an identity for } S \land \]
\[ s'(v_i) = \overline{h}(\lim_{P}(x, S)). \]

A $P_p$-isomorph-eliminating generator generates a $P_p$-limited value for each possible value or it generates a relabelling of the $P_p$-limited value. But a relabelling of the $P_p$-limited value is itself a $P_p$-limited value. Therefore, a $P_p$-isomorph-eliminating generator is a $P_p$-limiting generator.

**Lemma 23:** A $P_p$-isomorph-eliminating generator is a $P_p$-limiting generator.

**Proof:** Need to prove that $\forall S \in S_{i-1}. \forall s' \in g_i(P)(S). s'(v_i)$ is $P_p$-limited.

By definition, $\exists x. s'(v_i) = \overline{h}(\lim_{P}(x, S))$.

Because $\overline{h}$ is an identity for $S$ and $\text{FV}(P) \subseteq \text{dom } S$ and $\text{FV}(p) \subseteq \text{dom } S$,

$\overline{h}(\overline{S}(P)) = \overline{S}(P)$ and $\overline{h}(\overline{S}(p)) = \overline{S}(p)$.

If $V_i \in \text{Var}_{\text{scalar}}$,

$\lim_{P}(x, S) = x$

By definition, $x \in \overline{S}(P) \Rightarrow \overline{h}(x) \in \overline{h}(\overline{S}(P))$

Because $\overline{h}(\overline{S}(P)) = \overline{S}(P)$, $\overline{h}(x) \in \overline{S}(P)$

Therefore, $S'(v_i)$ is $P_p$-limited.

If $V_i \in \text{Var}_{\text{set}}$

$\lim_{P}(x, S) = x \cap \overline{S}(P)$

so $\overline{h}(\lim_{P}(x, S)) = \overline{h}(x) \cap \overline{h}(\overline{S}(P))$

so $\overline{h}(\lim_{P}(x, S)) = \overline{h}(x) \cap \overline{S}(P)$

Therefore, $S'(v_i)$ is $P_p$-limited.

If $V_i \in \text{Var}_{\text{rel}}$

$\lim_{P}(x, S) = x \cap \overline{S}(P) \times \overline{S}(p)$

so $\overline{h}(\lim_{P}(x, S)) = \overline{h}(x) \cap \overline{h}(\overline{S}(P) \times \overline{S}(p))$

so $\overline{h}(\lim_{P}(x, S)) = \overline{h}(x) \cap \overline{S}(P) \times \overline{S}(p)$

Therefore, $S'(v_i)$ is $P_p$-limited.

Therefore, $g_i(P)$ is a $P_p$-limiting generator.
A \( Pp \)-isomorph-eliminating generator is also \( Pp \)-limited sound.

**Lemma 24:** A \( Pp \)-isomorph-eliminating generator \( g_i^{Pp} \) is \( Pp \)-limited sound for \( \Pi d(\phi) \).

**Proof:** Assume \( s \in S_N \land \phi[s] = \text{true} \).

Need to find an element \( s' \in S_N : s \approx_{\Pi d(\phi)} s' \land \text{Var}_i \land s' \in g_i^{Pp}(\text{Var}_{i-1} \land s) \)

By definition, \( \exists s'' \in g_i^{Pp}(\text{Var}_{i-1} \land s) \).

\( \exists h, h(s(v_i)) = s''(v_i) \land h \) is an identity for \( \text{Var}_{i-1} \land s \).

Therefore, \( h((\text{Var}_i \land s) = s'' \).

Therefore \( \exists s' \in S_N : s \approx_{\Pi d(\phi)} s' \land \text{Var}_i \land s' = s'' \).

Therefore, \( \text{Var}_i \land s' \in g_i^{Pp}(\text{Var}_{i-1} \land s) \).

Together, a \( Pp \)-isomorph-eliminating generator and a bounded-generation generator generate fewer assignments than either a simple isomorph-eliminating generator or a bounded-generation generator paired with an exhaustive-enumeration generation. The combination, however, is still sound, now for the combination of an appropriate partial assignment duplication with the permutation duplication.

**Theorem 25:** If \( v_i \in \text{Var}_{\text{scalar}} \) and \( g_i^{Pp} \) is a \( Pp \)-limiting isomorph-eliminating generator, then the level \( i \) bounded generator \( bg_i^{Pp R} \) using \( g_i^{Pp} \) is sound for \( \Pi d(\phi, v_i \in P) \circ \Pi d(\phi) \).

**Proof:** Assume \( s \in S_N \) such that \( \phi[s] = \text{true} \).

Need to prove \( \exists s' \in S_N : s' \approx s' \land \text{Var}_i \land s' \in bg_i^{Pp R}(s) \).

Because \( \phi[v_i \in P, \forall s \in S_N, \phi[s] = \text{true} \Rightarrow s(v_i) \in s(P) \)

By definition, \( s(v_i) \in s(P) \Rightarrow \text{limit}_{i}^{Pp}(s(v_i)) = s(v_i) \)

Therefore, \( \forall s \in S_N, \phi[s] = \text{true} \Rightarrow \text{limit}_{i}^{Pp}(\text{Var}_i \land s) = \text{Var}_i \land s \).

By Lemma 24, \( g_i^{Pp} \) is \( Pp \)-limited sound for \( \Pi d(\phi) \).

Therefore, \( g_i^{Pp} \) is sound for \( \Pi d(\phi) \).

Therefore, by Theorem 9, \( g_i^{Pp} \) is sound for \( \Pi d(\phi) \).

Since \( bg_i^{Pp R} \) simply passes through the assignments generated by \( g_i^{Pp} \),

\( bg_i^{Pp R} \) is sound for \( \Pi d(\phi) \).

**Theorem 26:** If \( v_i \in \text{Var}_{\text{set}} \) and \( g_i^{Pp} \) is a \( Pp \)-limiting isomorph-eliminating generator, then the level \( i \) bounded generator \( bg_i^{Pp R} \) using \( g_i^{Pp} \) is sound for \( \Pi d(\phi, v_i \in (P \cup R) \land \forall i \land \forall \phi) \circ \Pi d(\phi) \).

**Proof:** Assume \( s \in S_N \) such that \( \phi[s] = \text{true} \).

By definition of \( g_i^{Pp} \)

\( \exists s' \in g_i(s) : \exists h, h \) is an automorphism \( \land h \) is an identity for \( s \land \)
\[ S'(v_i) = \tilde{h}(\text{limit}^{P}(S(v_i), S)). \]

Therefore, \( \tilde{h}(\text{limit}^{P}(\text{Var}_i < S)) = S' \).

By definition, \( \text{limit}^{P}(\text{Var}_i < S)(v_i) = S(v_i) \cap S(P) \).

Because \( \phi \vdash (P \cup R) \land R \vdash v_i \),
\[ \phi \vdash v_i \vdash (P \cup R) \land \phi \vdash R \vdash v_i \]

Therefore, \( \phi[s] = \text{true} \Rightarrow S(v_i) \subseteq S((P \cup R)) \land S(R) \subseteq S(v_i) \).

Therefore \( S(v_i) \subseteq S(P) \cup S(R) \).

Therefore, \( S(v_i) \subseteq (S(v_i) \cap \tilde{S}(P)) \cup \tilde{S}(R) \).

Because \( \tilde{S}(R) \subseteq S(v_i), (S(v_i) \cap \tilde{S}(P)) \cup \tilde{S}(R) \subseteq S(v_i) \).

Therefore, \( (S(v_i) \cap \tilde{S}(P)) \cup \tilde{S}(R) = S(v_i) \).

Therefore, \( \text{limit}^{P}(\text{Var}_i < S)(v_i) \cup \tilde{S}(R) = S(v_i) \).

Therefore, \( \text{limit}^{P}(\text{Var}_i < S) = \tilde{S}(\text{Var}_i < S) \).

Therefore, \( \tilde{h}(\text{Var}_i < S) = S' \).

Therefore, \( \exists S'' \in S_N, \tilde{h}(S) = S'' \).

Therefore, \( S = S'' \land \text{Var}_i < S'' \in g(S) \).

Theorem 27: If \( v_i \in \text{Var}_{rel} \) and \( g^{P} \) is a \( P \)-limiting isomorph-eliminating generator, then the level \( i \) bounded generator \( b_g^{P} \) using \( g^{P} \) is sound for \( \text{PA} \) \( (\phi, (\text{dom } v_i \leq P \land \text{ran } v_i \leq P)) \) \( \vdash \phi \).

Proof: By a similar argument to the one used to prove Theorem 26.
5. Derived Variables and Short Circuiting

This section formalizes the selective enumeration techniques called derived variables and short circuiting, which were introduced by example in the first section. Each technique will be proven sound.

These techniques are far simpler than isomorph elimination or bounded generation. These techniques also lack the complications of combining techniques found with bounded generation and isomorph elimination.

5.1 Overview of Derived Variables

A derived variable is one that has a constructive derivation. Typically, one of the atomic formulae conjoined in the formula being analyzed gives an explicit value for the variable. This occurs several places in the example claim uniqueAddrAlloc. In the schema Heap, the atomic formula used = dom usage restricts used to a single value for each value of usage. Similarly, usage could be derived from the variables used and usage', using the atomic formula (used \(\leq\) usage'). Clearly, the use of one of these derivations invalidates the other; either usage must be generated before used or used must be generated before usage. The derivations available is both an input to and a result of the choice of variable ordering.

Derived variables can be considered as the ultimate application of bounded generation. For derived variables, the value of the variable is determined by the value of a term that I call \(T\). A scalar variable is a derived variable if the bounded generation term \(P\) is limited to a single element for all possible partial assignments. The term \(T\) defines that single element. Similarly, a set variable is a derived variable if the best bounded generation term \(P\) is empty for all assignments; in this case the derivation term \(T\) is the same as the bounded generation term \(R\). The limitations on bounded generations of relations prohibit a direct equivalence with derived variables, however.

5.2 Definition of Derived-Variable Generation

A variable may be derived if the value is constrained to a single term and that term involves only variables that precede the derived variable in Ord.

**Definition 47:** For a term \(T\), a level \(i\) generator \(g_i(T)\) is a derived-variable generator for formula \(\phi\), iff
\[
\phi \vdash \forall v_i = T \land FV(T) \subseteq \text{Var}_{i-1} \land \forall s \in S_{i-1}. g_i(T)(s) = s \cup \{v_i \mapsto \overline{s}(T)\}
\]

A derived-variable generator is always sound for any duplication.

**Theorem 28:** A level \(i\) derived-variable generator \(g_i(T)\) for formula \(\phi\) is sound for any duplication \(d(\phi)\).

**Proof:** Let \(s \in S_{N+1} : \phi[s] = \text{true}\).

Because \(\phi \vdash v_i = T\), \(\Rightarrow s(v_i) = \overline{s}(T)\).

Therefore \(\text{Var}_i \triangleleft s \in g_i(T)(\text{Var}_{i-1} \triangleleft s)\)
5.3 Overview of Short Circuiting

Short circuiting is more of a post-filter than a generator technique. Short circuiting removes all remaining partial assignment duplicates. Given a set of formulae that must be satisfied, short circuiting removes any partial assignments that fail to satisfy one or more of the formulae.

In the example considered earlier, bounded generation had limited the values generated for usage such that the domain of usage was a subset of the domain of usage' and the range of usage was a subset of the range of usage'. The formula, however, includes a stronger constraint: (used = usage'). Short circuiting removes any partial assignments involving used, usage, and usage' that fail to satisfy this constraint.

Like bounded generation, a short-circuiting generator depends on another generator to produce assignments, modifying the set of assignments generated. Unlike bounded generation, a short-circuiting generator may suppress some assignments generated by the underlying generator, preventing their consideration in the next level of the search.

5.4 Definition of Short Circuiting

A short-circuiting generator requires a set of formulae, referred to as \( \mathcal{F} \), and an underlying generator. The short-circuiting generator yields every assignment yielded by the underlying generator that satisfy all of the formulae within \( \mathcal{F} \).

**Definition 48:** For a set of formulae \( \mathcal{F} \), a level \( i \) generator \( g_i^{\mathcal{F}} \) is a short-circuiting generator for formula \( \phi \) using a level \( i \) generator \( g'_i \) iff

\[
\forall f \in \mathcal{F}.(\phi \models f \land \forall s \in S_{i-1}, g_i^{\mathcal{F}}(s) = \{s' \mid s' \in g'_i(s) \land \models f[s'] = \text{true})\).
\]

A short-circuiting generator is sound if the underlying generator is sound.

**Theorem 29:** A level \( i \) short-circuiting generator \( g_i^{\mathcal{F}} \) for formula \( \phi \) using a level \( i \) generator \( g'_i \) is sound for \( \text{PAD}(\phi, \phi') \circ d(\phi) \) if \( g'_i \) is sound for \( d(\phi) \) where \( \phi' \) is \( f_1 \) and \( f_2 \) and \( f_3 \) ... and \( f_i \) with \( f_1 \cdots f_i \in \mathcal{F} \).

**Proof:** Proof by construction.

Assume \( s \in S_n, \models \phi[s] = \text{true.} \)

Because \( g'_i \) is sound for \( d(\phi) \), \( g'_i \) is sound for \( \text{PAD}(\phi, \phi') \circ d(\phi) \) by Theorem 9.

Therefore, \( \exists s' \in S_n, s \approx s' \land \forall \text{Var}_{i-1} \triangleleft s \in g'_i(\text{Var}_{i-1} \triangleleft s). \)

Because \( \models \phi[s] = \text{true} \land s \approx s', \models \phi[s'] = \text{true.} \)

Because \( \forall f \in \mathcal{F}. \phi \models f, \forall f \in \mathcal{F}. \models f[s'] = \text{true.} \)

Therefore, \( s' \in g_i^{\mathcal{F}}(s). \)

\[\blacksquare\]
6. Refining the Model

The model of selective enumeration developed thus far is somewhat limited. The first subsection here re-introduces given types. Given types are a partitioning of \( U \) that limits the acceptable values for variables. The NP language allows relational variables to be limited to subsets of \( \text{Value}_{\text{rel}} \), such as functions, injections, or surjections. Limiting the variable to denote only relations that are functions is the most common of these limitations. The second subsection will focus on this functional limitation.

6.1 Reconsidering Given Types

Given types are disjoint subsets of \( U \), the universe of elements. In NP, a variable or expression is not simply restricted to denoting a scalar, set, or relational value; instead, it is restricted to denoting an element of a given type, or a subset of a given type, or a relation drawn from the cross product of given types.

This information is most easily captured as additional constraints on the formula under consideration. For example, the uniqueAddrAlloc claim is translated and negated into Formula 3; in addition to the requirements given by Formula 2, the first four lines represent the constraint implied by the use of the given types in the variable declarations.

**Formula 3:** \( \phi = ( ( ( ( \text{dom usage} <= \text{Addr} \text{ and ran usage} <= \text{Value}) \text{ and} \text{ (dom usage'} <= \text{Addr} \text{ and ran usage'} <= \text{Value}) \text{ and} \text{ (used'} <= \text{Addr} \text{ and used} <= \text{Addr}) \text{ and} \text{ a in Addr}) \text{ and} \text{ (dom usage = used and dom usage'} = \text{used'}) \text{ and} \text{ (func usage and func usage'} ) \text{ and} \text{ ( (used} <= \text{usage'}) = \text{usage and used'} = (\text{used U \{a\}}) \text{ and a in used}) ) )

This new formula uses two new variables, Addr and Value, representing the two given types. These variables are generated before any standard variables using a special generator, called a scope generator. The scope generator uses the scope, a user-provided mapping from given type to a number of elements desired in each given type.

**Definition 49:** Variable_{all} = Variable_{scalar} \cup Variable_{set} \cup Variable_{rel} \cup Variable_{type}

**Definition 50:** A function \( \sigma: \text{Variable}_{type} \rightarrow 1..N \) is a Scope iff \( \sum \text{ran} \sigma \leq N \)

**Definition 51:** A scope generator \( \text{sg}: \text{Variable}_{type} \times \text{Scope} \rightarrow P'U \) is defined as
\[
\text{sg}(t, \sigma) = T. |T| = \sigma(t) \land R 
\Rightarrow x \in T \Rightarrow x \in \bigcup \text{sg}(t_i, \sigma)
\]

Bounded generation and derived variables can now guarantee that only values satisfying the given type constraints will be generated.

This does have a notable practical effect on isomorph elimination, however. Because the given types will always be generated first, only automorphisms that do not map any elements between given types will be identities over any partial assignment. Therefore the additional reductions
gained by bounded generation includes many reductions lost in isomorph elimination. However, this restriction can also be used to advantage in the implementation of isomorph elimination; a much smaller space of automorphisms need be considered during generation.

6.2 Limiting Relations to Functions

The original specification restricted the values of usage and usage' to be functions, whereas the translated formula allowed these variables to be mapped to any relation. A further improvement on the formula translation is required. Formula 4 adds another constraint involving these variables to the formula given in Formula 3.

**Formula 4:**  
\[ \phi = ( (( ( ( \text{dom usage} \leq \text{Addr} \text{ and ran usage} \leq \text{Value}) \text{ and} \\
                   ( \text{dom usage}' \leq \text{Addr} \text{ and ran usage}' \leq \text{Value}) \text{ and} \\
                   ( \text{used}' \leq \text{Addr} \text{ and used} \leq \text{Addr}) \text{ and} \\
                   a \text{ in Addr}) \text{ and} \\
                   ( \text{func usage and func usage}' ) \text{ and} \\
                   ( \text{dom usage} = \text{used} \text{ and dom usage}' = \text{used}') \text{ and} \\
                   ( \text{func usage and func usage}' ) \text{ and} \\
                   ( ( \text{used} \leq \text{usage}') = \text{usage and used}' = (\text{used U \{a\}}) \text{ and} \\
                   a \text{ in used}) \text{ (used U \{a\})} \text{ and an in used} \) \]

Short circuiting could easily handle these additional constraints directly by including func usage and func usage' as two of the formulae in F. However, this misses some important opportunities to further reduce the number of assignments generated.

The exhaustive-enumneration generator and the isomorph-eliminating generators can be easily enhanced to generate only functions. Bounded generation can also be extended to take advantage of this case without much effort.

**Definition 52:** For any \( P, p, R \in \text{Term}_{\text{set}} \) and \( E \in \text{Term}_{\text{rel}} \), a level i generator \( \text{bg}_{i}^{p, \phi_{RE}} \) is a function-aware bounded generator for \( \phi \) using a \( P \)-limiting generator \( \text{g}_{i}^{p} \), iff  
\[ \text{FV}(P) \subseteq \text{Var}_{i-1} \wedge \text{FV}(p) \subseteq \text{Var}_{i-1} \wedge \text{FV}(R) \subseteq \text{Var}_{i-1} \wedge \text{FV}(E) \subseteq \text{Var}_{i-1} \wedge \\
(V_{i} \in \text{Var}_{\text{set}} \Rightarrow \phi \vdash v_{i} \in P \wedge p = \{ \} \wedge R = \{ \} \wedge E = \{ \} \wedge \text{bg}_{i}^{p, \phi_{RE}}(s) = g_{i}^{p}(s) \wedge \\
(V_{i} \in \text{Var}_{\text{rel}} \Rightarrow \phi \vdash v_{i} \in \{ P \cup R \wedge \phi \vdash R \leq v_{i} \wedge p = \{ \} \wedge E = \{ \} \wedge \text{bg}_{i}^{p, \phi_{RE}}(s) = \{ s' \mid \exists s'' \in g_{i}^{p}(s). s'=s'' \cup \bar{s}(R) \}) \wedge \\
(V_{i} \in \text{Var}_{\text{rel}} \wedge \phi \vdash \text{func } v_{i} \Rightarrow \phi \vdash \text{dom } v_{i} \in \{ P \cup \text{dom } E \wedge \phi \vdash \text{ran } v_{i} \leq p \wedge \phi \vdash E \leq v_{i} \wedge R = \{ \} \wedge \text{bg}_{i}^{p, \phi_{RE}}(s) = \{ s' \mid \exists s'' \in g_{i}^{p}(s). s'=s'' \cup \bar{s}(E) \}) \wedge \\
(V_{i} \in \text{Var}_{\text{rel}} \wedge \neg \phi \vdash \text{func } v_{i} \Rightarrow \phi \vdash \text{dom } v_{i} \leq P \wedge \phi \vdash \text{ran } v_{i} \leq p \wedge R = \{ \} \wedge E = \{ \} \wedge \text{bg}_{i}^{p, \phi_{RE}}(s) = g_{i}^{p}(s)) \]
This generator works for functions much the way the original generator works for sets. $\mathcal{E}$ is a term describing a set of edges that must be included in any value generated. Because the value must be a function, the domain of $\mathcal{E}$ can be excluded from $\mathcal{P}$. 
7. Conclusion

This paper has introduced a formal framework for describing selective enumeration and the techniques that implement it. In related papers, I define specific algorithms for implementing each technique and show that they lead to sound generators. I also define an algorithm for discovering a set of constraining formulae, as needed by partial assignment duplications, and an algorithm for selecting an ordering that takes substantial advantage of the reduction opportunities.

7.1 Future Work

One potential future direction is the search for additional forms of duplication. Although the two duplications I describe in this paper are effective at reducing the number of assignments generated, further duplications would enable additional specifications to be analyzed.

Another possible direction is analyzing different input languages. A promising candidate is OCL[IBM97], the constraint language recently defined for the object specification notation UML. Most of OCL can be directly translated into the formula language I use here. The object orientation introduces some new concepts, particularly inheritance, that require additional consideration and may enable additional constraints.

A final possible direction involves applying the general approach of selective enumeration to incremental search problems in other, non-relational domains. If any easily computable features can be defined that distinguish interesting and non-interesting instances, the framework I described in this paper can be applied.

As an example, consider the problem of TF-sensitive test generation [CM94]. A test \( T \) for a boolean expression \( E \) is sensitive to a variable \( x \) in \( E \) if changing only the value of \( x \) changes the result of \( T \) for \( E \). The goal in test generation is to obtain a near-minimal test set that contains at least one test that is sensitive for each variable. Like the relational satisfaction problem, the general solution is exponential.

Conceptually, a selective-enumeration-like search could be used to find such a set. It seems likely that techniques could be developed that efficiently rule out tests as duplicates if they are not sensitive to any variables not already tested by a test in the set.
